The efficiency of the salt mixture found in milk has been demonstrated in experimental laboratories for years. In the early nutrition studies milk itself was used as a source of the inorganic salts. Later, in an attempt to ascertain the nature of the factors in milk which stimulated growth in rats, an artificial salt mixture was prepared the composition of which was designed to simulate

that of milk ash as closely as possible. Additional iron, of course, had to be incorporated. This salt mixture was found to be very satisfactory and is now used in many laboratories to supply the mineral requirements in experimental studies with animals.

THE VITAMINS.

Milk contains all the vitamins which have been shown to have been necessary for man but, with the possible exception of vitamin A, cannot be considered a rich source of any of them. Consequently, milk should never be fed as the sole supply of these dietary essentials. During growth the demand for vitamins is so great that it is not always possible for the baby to consume as much milk as is required to furnish some of them in sufficient amount. For this reason many pediatricians prescribe cod liver oil and tomato juice or orange juice as early as the third week of life. Likewise, the adult who may be forced to subsist largely on a milk diet, must have access to foods more concentrated in the vitamins.

Vitamin A.—From observations that had been made of the presence of vitamin A in milk fat it was noticed that animals grew well for a certain period on various mixtures of purified food materials but they ultimately declined rapidly in weight and died unless butterfat were included in the diet. This led at first to the view that butter contains an unknown substance, the chief function of which is to promote growth. Later, when the diets were more carefully refined and purified and contained little if any natural food, it was found that the absence of butterfat from the food not only brought about a rapid decline in weight, but also gave rise to a definite pathological condition of the eye characterised by a dryness of the tissues and their subsequent invasion by bacteria. The unidentified substance in butterfat which prevented it was designated vitamin A.

Xerophthalmia has been observed in children who did not have access to liberal amounts of a good milk, butter, eggs, yellow or green vegetables, or cod liver oil. Numerous cases occurred in Denmark during the early years of the World War when margarines were substituted in the diet for butter, which was being exported. From 1917 to 1919 the exportation of butter was forbidden, and this eye lesion disappeared.

The vitamin A content of human milk may be equivalent to that of cows' milk, but its presence in any milk is dependent entirely on the amount taken in in the mother's diet. It is believed that the vitamin A of mothers' milk, although no more concentrated than in cows' milk, is more completely utilised by the infant, even if identical amounts of the vitamin are given in the form of cows' milk. Since vitamin A is confined to the cream portion, about 90 per cent. is removed by the process of skimming. Therefore, skimmed milk formulas would fail to furnish the baby with sufficient vitamin A, and this essential material must be supplied in some other way.

Although vitamin A is destroyed by prolonged exposure to air, and by heat and storage, the temperatures ordinarily reached in cooking and in the preparation of infant formulas only slightly diminished its original concentration in milk. In the most careful commercial evaporation or powdering of milks, no appreciable destruction of this vitamin results.

Vitamin B.—This vitamin is not plentiful in milk. Cows' milk is about one and one-half times richer than human milk, but, weight for weight, is less than one-fiftieth as potent as a good sample of dried brewery yeast. Vitamin B is soluble in water and therefore is contained in the skimmed milk portion. It is fairly resistant to heat and oxidation and thus is unaffected by ordinary cooking, by desiccation, or evaporation.

Like vitamin A, this vitamin is present in the milk only to the extent that it occurs in the maternal diet and, since it is not stored in the body during periods of plenty, its absence from the food is quickly reflected in the quality of the milk.

The vitamin B content of human milk varies inversely with the quantity secreted. Thus women who produce large quantities of milk may be supplying their babies with a food far below the optimum in vitamin B. Since the rate of growth of experimental animals can be retarded or accelerated at will by the amount of vitamin B administered in their diet, it is evident that some other source of it than the mother's milk must frequently be supplied in order to ensure the normal growth of the young.

Vitamin C.—Milks, even in a fresh condition, are rather poor sources of the scurvy-preventing substance, vitamin C. Summer milk may be richer than winter milk, but this is dependent on the type of fodder fed. Herds that receive the same ration winter and summer, without access to fresh green pasturage, will probably produce a milk constant in its vitamin C value although carrying a minimal amount.

Vitamin C is quickly destroyed by oxidation and by exposure to air and heat, hence the milk delivered to the average consumer is relatively deficient in this substance. Milk quickly boiled without stirring may retain most of its vitamin C, but pasteurisation at 60dg. C. for 30 minutes will destroy it almost completely. Evaporated milk and sweetened condensed milk are consequently nearly devoid of it. Milk powders vary in their vitamin C content with the process of manufacture. The roller process leads to somewhat less destruction of this vitamin than does the spray process.

Since milks contain so little vitamin C, even when freshly secreted, and since destruction occurs so readily on exposure to air and to high temperatures, it is imperative that adults as well as children should be assured of other sources of vitamin C. Liberal portions of fresh fruit juices, fruits, and vegetables are necessary to forestall the bleeding and tenderness of the gums, the loosening of the teeth and the swollen and tender joints that are symptomatic of scurvy.

Vitamin D.—Milks in general very seldom contain sufficient vitamin D to prevent or cure rickets in babies. Assays of human milk have revealed an almost total absence of this factor, although cows' milk probably contains a small amount. As is the case with the other vitamins the concentration in the milk depends somewhat on the access of the cow to foods rich in vitamin D. It is not possible, however, to increase the potency of human milk by dietary means. Exposure of the lactating mother to sunshine or to artificially produced ultra-violet light will stimulate the secretion of vitamin D into her milk. This is true, also, for the goat. Similar exposure of the cow does not thus enrich the milk. Vitamin D is not readily destroyed by heat, therefore ordinary boiling or pasteurization may be carried out with impunity. Commercially evaporated milks have been shown to be as potent as are pasteurised milks in inducing maximal calcification of bones.

It is a curious fact that, although average human milks contain little demonstrable vitamin D, rickets develops less often and in far less severity in exclusively breast fed children. It is yet to be learnt whether the explanation of this lies in the high lactose content of human milk, in the concentration of its inorganic salts, or in both.

It should be stressed that no milk, either human or cows', can furnish enough vitamin D to the rapidly growing infant to allow for the perfect development of its bones. Intake of cod liver oil, or egg yolk, and exposure to the unobstructed rays of the sun should be begun in the early weeks of life.

Vitamin E.—This is the dietary factor that has been found in experimental studies to be essential for successful reproduction in the albino rat. Its value for the human species has not as yet been proved. The concentration in cows' milk is extremely small, even when the ration of the cow contains ample portions of fresh lucerne. Since the vitamin is found in the fat fraction, skimmed milk is devoid of it. Human milk has not been tested for its vitamin E content. Destruction due to heating and oxidation does not readily occur.

Vitamin G.—Pellagra, a serious disease that is prevalent in the southern part of the United States, has been found within recent years to be of dietary origin. It may be prevented or cured by a substance of unknown composition in milk, glandular meats, yeast, and also in certain vegetables. Liberal quantities of cows' milk must be ingested if this food supplies the only source of the pellagra-preventing vitamin G. Human milk contains less of it than is found in cows' milk. Evaporated, condensed, and dried milk have not been studied for their vitamin G content, but since it is known to be extremely resistant to heat, it is probably present to the same extent as in raw or pasteurised milk.

ENERGY VALUE OF MILK.

Because of its large water content, whole milk has a relatively low energy value per unit of weight. Table III. on page 909 of the February *Journal* shows the calorific value of milk and of different milk products. The figure there given, 315 calories per pound, indicates that an average person would require about 3½ quarts daily to supply the needed 2,500 calories of energy. A person employed at vigorous manual labor would need nearly twice as much. Milk is manifestly unsuited to serve as the sole food of adult man, not only because of the deficiencies mentioned in the previous sections, but also because of its low energy value. However, its value as one of the fundamental constituents of a well chosen dietary can hardly be over-emphasised.

(To be continued.)

SUMMER SWEETS AND DISHES.

[Paper read by Miss I. Sires at the March meeting of the Wasleys Branch.]

BAKED APPLE AND FIG CUSTARDS.

Ingredients.—½lb. cooking apples (peeled and cored), 2ozs. figs, ½oz. shelled walnuts, ¼ gill water, 2 dessertspoons sugar, 1 whole egg, 1 white of egg, ¼ gill milk, 1 tablespoon castor sugar, ¼ level teaspoon ground cinnamon, finely grated orange rind. **Method.**—Peel, core, and slice apples (½lb. prepared), stew with water and sugar. Stew until tender, then mash them up finely, cut up figs and chop walnuts. Beat the whole egg and mix it with milk. Stir all into the mashed apples when they have cooled slightly, then turn mixture into a pie dish and bake it until set without letting it boil. Whisk the egg white to a stiff froth, mix cinnamon with castor sugar, and fold it into the egg white lightly, then heap it on top of custard. Dredge the top of the egg-white with sugar, and put into cool oven to set. Serve cold with finely grated orange rind sprinkled on top if cared for. Sufficient for 3 persons.

COFFEE BLANC MANGE.

Ingredients.—1 pint milk, 1½ozs. cornflour, coffee essence, ½oz. butter, 1½ dessertspoons sugar. **Method.**—Smooth the cornflour with a small quantity of the milk and heat the remainder of the milk in a saucepan with the sugar. Pour this on to the mixed cornflour then return it all to the pan and bring it to the boil, keeping it well stirred. Boil gently for a few minutes then add the butter and sufficient coffee essence to flavor, and more sugar if required. Turn the blanc mange into a mould rinsed with cold water, and when set unmould it and serve it with cream. Sufficient for 4 persons.

PEACH CUSTARD.

Ingredients.—1doz. good juicy peaches, 1 cup castor sugar, 1 pint milk, 3 eggs, 1 tablespoon cornflour, few drops essence lemon. **Method.**—Skin peaches, break in halves and remove stones, put into a piedish, sprinkle sugar over and stand 2 or 3 hours. Make a custard of the milk and yolks of the eggs. Make rather

thick by adding a good tablespoon of cornflour. Add essence and stir occasionally while cooling. When nearly cold, pour over the peaches. Whip the whites of eggs to a very stiff froth, add 2 tablespoons castor sugar, stir in lightly and spread over custard. Put in a hot oven for a few minutes to set, until a pale fawn color.

RICE JELLY MOULD.

Ingredients.—1 pint packet jelly, left over fruit juice (about $\frac{3}{4}$ pint), $\frac{1}{4}$ lb. rice. *Method.*—This is a good way of using up left over fruit juice from tinned or bottled fruits, or jelly made with water. Choose a jelly that will blend with the flavor of whatever juice is being used, such as plum juice for raspberry or strawberry jellies, pineapple, apricot, pear, or peach juice for lemon or orange jellies. Heat the juice and dissolve the jelly in it, making it up to 1 pint with the jelly. Wash the rice and cook it in boiling water until tender, drain well and stir into dissolved jelly. Add sugar if required and leave until it begins to thicken and then turn into a wet mould. Unmould the rice jelly when set and serve with custard or cream.

APPLE CUSTARD.

Ingredients.—2lbs. good cooking apples, $\frac{3}{4}$ pint water, add more water if necessary, 4 eggs, 6ozs. sugar. *Method.*—Make a syrup of water and sugar, peel and core the apples and cook gently in the syrup until tender. Rub through a sieve, beat eggs, stirring well. Cook over the fire gently, but do not boil; serve cold in custard glasses.

SUBSTITUTE FOR WHIPPED CREAM.

Ingredients.—1 pint milk, 1oz. butter, 2ozs. castor sugar, 2 eggs, $\frac{1}{4}$ oz. gelatine, few drops essence vanilla. *Method.*—Soak gelatine in a little of the milk for 1 hour. Put remainder on to boil, cream butter and sugar, add yolks of eggs and beat. Pour in a little of the boiling milk, then gradually add the remainder. Stir in gelatine and cook very gently until gelatine is dissolved, taking care the eggs do not curdle. Allow to cool slightly then add the vanilla and whites of eggs beaten to a stiff froth. Stir in lightly and put aside to cool.

COCOA MOULD.

Ingredients.—2 eggs, 1 pint milk, 1 dessertspoon cocoa, $\frac{1}{4}$ oz. gelatine, $\frac{1}{2}$ gill water, vanilla flavoring, 2 $\frac{1}{2}$ dessertspoons sugar. *Method.*—Mix cocoa to a smooth paste with a spoonful of milk, heat remainder and add to cocoa, then return all to the pan and bring to the boil. Boil for a minute or two, then take off fire and cool slightly. Beat eggs, add cocoa, milk (hot but not boiling), then turn the mixture into the top of a double boiler and add sugar. Stir until custard thickens, then remove it and leave it to get cold. Dissolve gelatine in a saucepan with water, then strain it into the cold custard. Flavor it with vanilla and add more sugar if required. Leave custard until it is beginning to thicken, then turn it into a wet mould to set. Unmould the mixture and serve plain or with cream.

PUDDINGS, STEAMED AND BOILED.

(Miss P. Richter.)

With a foundation mixture for a plain steamed pudding such as 2 tablespoons butter, 3 tablespoons sugar, 1 egg, 1 cup milk, 2 small cups S.R. flour, and steaming for 1 $\frac{1}{2}$ hours several different kinds of puddings can be obtained. By adding 1 tablespoon of cinnamon it gives a nice brown pudding that can be served with either custard or white sauce. The same mixture can be made as a waterfall pudding by placing 3 tablespoons of dark jam in the steamer before putting in the mixture. Golden syrup can be used in the place of jam if preferred. If the mixture is left plain it can be served with jam sauce, made by using 1 cup water, 1 $\frac{1}{2}$ tablespoons sugar, 1 tablespoon dark jam, and thicken with cornflour. Stale cake can be used for puddings with the addition of fruit and spice, pour custard over and either steam or bake.

DRIED APRICOT STEAMED PUDDING.

Ingredients.—2 cups S.R. flour, 2 cups dried apricots (soaked overnight), 1 dessertspoon butter, 2 tablespoons sugar, pinch of salt, enough milk to make a stiff dough. Rub butter into flour and salt, add sufficient milk to make a stiff paste, roll out lightly and cut into four circles. Place 1 cup of apricots in the bottom of a greased basin, add little sugar, then layer of paste, then a layer of apricots sprinkled well with sugar; another layer of paste, and continue until the basin is full, making top layer pastry. Steam 3 hours, serve with custard or apricot sauce made thus:—Strain the water in which the apricots were soaked overnight, add $\frac{1}{2}$ cup sugar and boil; thicken with a little cornflour.

BAKED ROLY POLY PUDDING.

Raspberry Roll.—Mix 2 cups S.R. flour and 1 tablespoon dripping, add enough milk to form a stiff dough. Roll out and spread thinly with raspberry jam. Place in a pie-dish and pour the following sauce over the roll:—1 cup of boiling water, 1 tablespoon butter, 1 tablespoon sugar. Bake in moderate oven for $\frac{3}{4}$ hour. Thinly sliced apples sprinkled with sugar may be used instead of jam. Boiled puddings are usually made with suet, put into a scalded floured cloth and kept boiling. If allowed to go off the boil they will be heavy. They are usually served with a sweet sauce, or if the weather is hot the Christmas pudding is nice served with whipped cream.

CHRISTMAS PUDDING.

Ingredients.— $\frac{1}{2}$ lb. plain flour, $\frac{1}{2}$ lb. suet, $\frac{1}{2}$ lb. bread crumbs, $\frac{1}{2}$ lb. each of currants, sultanas, and raisins, $\frac{1}{2}$ lb. sugar (brown or white), 2ozs. shredded candied peel, 1 teaspoon mixed spice, 3 or 4 eggs, 1 wine glass brandy (optional), $\frac{1}{2}$ teaspoon carbonate soda dissolved in $\frac{1}{2}$ cup hot water, grated rind of $\frac{1}{2}$ lemon, $\frac{1}{2}$ teaspoon salt. This recipe is also suitable for putting into Fowler's jars, but in this case

butter should be used instead of suet. They will keep indefinitely and are handy in case of visitors. Fill the bottles two-thirds full and boil 4 hours.

A plain pudding more suitable for everyday use is 2 cups flour, 1 cup sugar, 1 cup raisins or currants, 1 tablespoon dripping, 1 teaspoon carb. soda; mix with boiling water; usually called boiling water pudding.

BAKED RHUBARB ROLL.

Ingredients.— $\frac{1}{2}$ lb. flour, 4 ozs. dripping, 1 dessertspoon castor sugar. Make into light crust and roll out thinly. Peel and cut rhubarb into small pieces, roll them in sugar, place on paste, sprinkle in few fine bread crumbs, roll as for ordinary jam roll, place in greased pie dish, brush over with white of egg and sugar. Bake nice brown and serve with custard or cream.

CABINET PUDDING.

Ingredients.—Butter inside of pudding mould, have ready 1 cup chopped citron, raisins, and currants. Sprinkle some of this fruit on bottom of mould, then slices of stale sponge cake. Shake over this some spice, cinnamon, cloves, and nutmeg, then fruit again and then cake until mould is nearly full. Make a custard of 1 quart milk, 4 eggs, pinch salt, 2 tablespoons melted butter, pour over cake without cooking it. Let stand and soak 1 hour; then steam $1\frac{1}{2}$ hours. Serve with sauce.

HOUSEHOLD INQUIRIES.

[Replies supplied by Miss E. Campbell, Dip. Dom. Econ., Education Department.]

Belalie Women's Branch asks—(1) How are pleated godets stitched into a skirt? (2) Should women and girls attend to the dairy herd on a farm? Replies—(1) Turn in the edge of the opening in the skirt about half an inch, and the top of opening should be carefully turned in perhaps only as much as quarter of an inch; it must be flat and might have to be snicked to allow it to set flat—then tack down. Place the godet under the skirt and stitch along the turned edge of skirt. The skirt must be on top of godet. The pleats at the top of godet should be made to lie flat, then on the inside of skirt, a small strip of binding should be placed across the top of godet and allowed to overlap the skirt about half an inch, then slipped stitched into position. This will keep the pleats in position, and will strengthen the join in the skirt. (2) It is generally recognised that it is a man's work to attend and care for stock of all kinds on farms, for there is often heavy, intricate, and sometimes unpleasant tasks to be performed. But the division of labor on a farm is an internal domestic affair, to be settled between the folk anxious for the welfare and advancement of the property.

Penola Women's Branch—(1) How to remove rain spots from a felt hat? and (2) Why does a blister sometimes rise on a sponge cake? Replies—(1) Steam the hat by allowing the steam from the spout of a kettle to pass into the crown of the hat, then as the steam works its way through the felt it will release the pile on the right side. With a stiff brush give the right side of the hat a good brushing, but care should be taken not to force the hat out of shape whilst it is damp. (2) If a sponge is put into an oven which is slightly too hot the surface will be hardened, and then when the interior is heated the air and gas in the mixture expands, if it is not thoroughly mixed and incorporated with the other ingredients, it will then come in one mass, and being unable to escape, as the surface has hardened, it will form a blister. Smaller strokes with the beater, when folding the flour into the egg and sugar, will often overcome this difficulty.

LEATHER FURNITURE.

Coonowarra Women's Branch asks—Why is it that American duck covered furniture (leather) becomes sticky after use? Reply—The imitation leather covering for furniture, commercially known as "Rexine," is made with a canvas backing and a mixture of paint and oil is worked well into the canvas. After the furniture has been in use for some time the canvas becomes pliable, and through climatic conditions the oil dries out of the surface, thus when heat is applied, either by the weather conditions or from the body heat of persons using the furniture, the leather stretches out of shape, and the paint mixture is slightly softened and becomes sticky. This cannot be permanently remedied, but by washing the surface over with a soft cloth, rinsed out of warm soapy water and immediately thoroughly dried. Then, when quite dry, rubbed well with an oily duster—linseed oil is the best—then rub with clean duster to remove any surplus oil. This will restore the Rexine for two or three months, or perhaps a little longer.

DRY TANNING A SHEEP SKIN.

Clare Women's Branch asks—(1) How to remove a stain from a cream flannel coat? (2) How to "dry tan" a sheep skin? Replies—It is impossible to give definite instructions until the nature of the stain is known, as each kind of stain requires a different treatment. Some general rules are as follows:—Always try weak chemicals first. Only have material in chemicals a short time, and then dip it into clean cold water. Do not rub too hard whilst in chemical. Wash out all chemicals before drying the article. Rub flannel material with a piece of flannel. (2) These directions are from the *Journal of the Department of Agriculture, South Africa*, page 55, July, 1922: Take two parts of saltpetre and one part of alum and reduce to a powder. Saltpetre is best, but if none is on hand use salt as a substitute. Rub well the flesh side of the skin with the powder, taking care that every part is covered with the mixture. Lay the skin away in a cool place for several hours. In cold winter weather it may be rolled up and left for a fairly long time. Next stretch it and allow it to dry a little, then scrape it, and before it is entirely dry, rub and twist it until it is entirely soft. It should be remembered that a solution has an advantage over dry tanning, because with the former there is little chance of any part of the skin escaping its effects.

GRASS STAINS.

Kangarilla Women's Branch asks—How to remove grass stains from cream trousers and silk dresses? Reply—Methylated spirits is used for the removal of grass stains. It is often necessary to allow the stain to soak in the spirits for a short time, then rub the stain with a piece of flannel dipped in the spirits, rubbing the way of the grain. Rinse the article in warm soapy water, the water should be just warm; hot water will often fix a stain. It might be necessary to repeat the process several times. Stains are always easier to remove if they are treated immediately they have occurred. Eucalyptus oil will also remove the stain, but the oil stain has to be removed later, and this is sometimes difficult.

HOW TO RID NEW BLANKETS OF UNPLEASANT ODORS.

Kybybolite Women's Branch asks—How to rid new blankets of unpleasant odors? Reply—Washing the blankets, using a deodorizer is the most satisfactory method of freeing blankets of any unpleasant odor. Sixpenny worth of formalin will be sufficient. With care the new appearance can be retained. Prepare sufficient cold, soapy water to cover the blankets, add to the water half of the formalin, then immerse the blankets. There should be a good lather on the water—dissolved Velvet soap and borax will produce a satisfactory lather.

Thoroughly wash the blankets by kneading and dollying—forcing the water through every particle of the blankets. When well washed pass the blankets through the wringer and then shake well to release and raise the pile. Pass them through two rinsing waters—both clear cold water with half of the remaining formalin added to each. Each time the blankets are passed through the wringer shake them well to raise the pile. Finally, rinse them in clear cold water, wring and shake well, then hang out on the line to dry, having only a small part of the blanket across the line. It will be found expedient to pull the blankets into a good shape when pegging them out. At frequent intervals change the position of the blankets from side to side in order to keep the moisture moving through the blankets instead of all draining to the one edge of the blankets, and it will avoid peg marks. When thoroughly dry the blankets should be their original size, perfectly white, very fluffy, and no trace of any unpleasant odor. A breezy, sunny day is best for washing blankets.

FERMENTING JAMS.

Kybybolite Women's Branch asks—What is the cause of jam fermenting after being opened a day or so? Reply—If jam has been boiled sufficiently to sterilize the fruit and to permit of the jam setting when tested, then put into perfectly clean and sterilized jars, and sealed, there should be no fermentation when the jars are opened and whilst it is being used. In selecting fruit for jam, care must be taken to see that the fruit is all perfectly clean and that no bruised, damaged, or diseased fruit is used. Three-quarters of a pound of sugar to each pound of fruit is a sufficient quantity of sugar to preserve the jam. Jam should not be watery when finished, as watery jam has not a good flavor, and it is liable to ferment. Jam should be stored in a dry, well ventilated cupboard and protected from dust.

MID-NORTH CONFERENCE (WOMEN'S SESSION), MARCH 14th, 1934.

The Branches of the Mid-Northern Agricultural Bureau held their Annual Conference at Laura on Wednesday, March 14th. The President of the Conference, Mr. H. R. Lines, extended a welcome to all those present, and expressed his desire that they would be much benefited by the Conference. The President then called upon the Hon. A. P. Blesing, M.L.C., Minister of Agriculture, who delivered a most able and interesting address.

For the afternoon session the women adjourned to an adjoining room, Mr. H. C. Pritchard declared the meeting open, and Mrs. R. P. Noble, of the Nelshaby Branch, was appointed President. The following papers were read:—

FEEDING AND CARE OF INFANTS.

[SISTER HARSLETT, Gladstone.]

Health is maintained by suitable food, fresh air, sunshine, exercise, regular habits, cleanliness of person, hygienic surroundings, sufficient sleep, and recreation. If a person is thus thoroughly healthy, with a sound mind in a sound body, he will offer a big resistance to any disease germ that comes along. His mental outlook will be bright and he will do good, intelligent work.

Mothers should realise that they are laying the foundation-stones for the future welfare and happiness of their children. In caring for the boys and girls of to-day they are caring for the fathers and mothers of the future. Each succeeding generation should be better than the preceding one.

The food of the expectant mother should be plain and good, easily digested, and such that will best nourish her baby. For example: milk, eggs, raw fruit, vegetables, and meat.

A baby's teeth are in the gums long before birth (about seven months before) and will be influenced by the diet the mother is taking. All rich, indigestible food must be excluded. All alcoholic drinks must be strictly avoided. Drugs and narcotics should not be taken. The mother must not smoke.

The ante-natal period, and the first few months after birth, may be considered the most momentous in the life of the individual, for growth or development taking place then is enormously rapid—foundations are being laid down for all time, and during this period of immaturity and greatest growth the organism is most likely to suffer permanent damage from deforming influences.

Speaking broadly, the important foods from the point of view of "building materials" are vegetables of all sorts—including raw salads to the greatest possible extent—fruits of all sorts, including dates, raisins, and other sun-dried varieties. Milk, and the products of milk, brown bread, and other unrefined cereals. If these essentials are adequately provided for, the rest of the diet will usually take care of itself.

Butter and eggs are important foods, and should not be stinted, but taken in moderation; meat should be taken only in strict moderation. Vegetables, fruit, milk, eggs, and whole cereals are selected for special mention, because all these foods are rich in mineral elements and vitamins. These are the constituents of food which are most likely to be lacking in an ordinary diet, and they are the very ones which are all-important for the building of sound bodies, especially the bones and teeth. One cannot too strongly emphasise the fact that a diet consisting largely of white bread, scones, tea, meat, and sweet stuffs, with little fruit, vegetables, and milk, is a deficient diet, and for the expectant and nursing mother it is calamitous. It utterly fails to provide adequately the essential elements for building up the various complicated and marvellous structures of the baby's developing body. Apart from the question of diet, the chief consideration for the expectant mother from the point of view of health affecting the baby are fresh air and sunshine, outdoor exercise, adequate rest, and complete freedom from chronic constipation.

If children have any defects or are abnormal in any way they should be promptly investigated and the children given the advantage of the best advice obtainable. Defective eyesight should be corrected; adenoids, diseased tonsils, decayed teeth, and other sources of infection should be removed. Very many diseases are fly-borne. Thousands of babies' lives are sacrificed every year through fly-carried diseases. Mothers should do all in their power to prevent contamination by flies. Mosquito-netting should be put over the baby's perambulator and cot. All food should be covered; kitchen refuse—scraps of food, &c.—should be wrapped in paper and put in a rubbish tin with a well-fitting lid. Houses should have doors and windows wire-netted to keep out flies. By exterminating flies, sandy blight, amoebic dysentery, gastro-enteritis and typhoid fever can almost be stamped out.

FEEDING.

Every baby ought to be breast-fed; nothing will ever equal the mother's milk. Her milk is the right composition that is required. It is exactly the right temperature, it is germ-free, it has the necessary vitamins which are damaged or destroyed when milk is heated. Another very important point is that the breast-fed baby has to work for his drink; this exercises his jaws, and stimulates all his digestive juices.

Babies bottle-fed on artificial food may appear all right, but children are much stronger ultimately if breast-fed. The risk of gastro-enteritis and such troubles are infinitely greater to the bottle-fed baby.

The importance of establishing and practising perfect regularity in the feeding times for babies is so great and the prejudice against waking an infant, if he happens to be asleep when feeding-time comes round, is so widespread that it is

necessary to specially insist on the point. All leading authorities of the day agree that the first thing to establish in life is regularity of habits. The mother who "can't be so cruel" as to wake her sleeping baby if he happens to be asleep at the appointed feeding-time, fails to realise that a few such wakings would be all she would ever have to resort to.

At the dawn of life a day or two of regular feeding with proper intervals (practically speaking, no normal baby needs to be fed more often than every three hours) suffices to establish clock-like regularity of alternate sleeping and feeding. The new-born babe should sleep nine-tenths of his time. At perfectly regular intervals the infant should wake, feed, and drop off to sleep again. Babies regularly and properly fed tend to sleep like dormice, digest their food well, and are infinitely more contented and happy than those whose mothers are irregular and unsystematic. The most reliable modern experience and research shows that even during the first month, feeding every four hours suits most babies, and no normal baby needs feeding more often than three-hourly. If a mother regulates her life, arranging everything for the baby's welfare, she will be rewarded with a healthy, regular, easily-managed baby, and will soon say he is no trouble at all.

To make a success it is very important that both the mother and the baby should have a good night's rest. From the very first the baby must not be fed during the night: that is, after 9 or 10 p.m. If he is fed every three hours from 6 a.m. to 9 p.m. he will get six drinks; a new-born could not do with less. If he is to sleep through the night without a drink, he must get enough nourishment during the day. Later on, about the third month, he can have only five meals a day—four hours apart—6 a.m., 10 a.m., 2 p.m., 6 p.m., and 10 p.m. respectively.

Baby will probably need five meals a day until he is nine months old. Baby will often like a drink of water between meals, especially in summer. Give him lukewarm boiled water with a cup and spoon. Train him to take water in this way and it will make it easier when weaning him. His orange juice may be given the same way.

If the baby is unhappy and has green stools something is wrong. It may be overfeeding, under-feeding, or aerophagy (that is, wind). Find out the total number of ounces of food the baby is getting in 24 hours. If the baby is over-fed there is regurgitation and the baby is well nourished. Diminish the supply by giving less and the intervals longer. If the baby is under-fed, increase the supply by complementary feeding of modified cow's milk and attention to the breasts by massage and fomentation.

It is very important to put the baby in an upright position after his drink, and sometimes during a drink, so that the airball in his stomach (due to air-swallowing) will rise to the top, where he can bring it up. While holding him upright, press gently over the lower ribs on the left side. If the baby is laid down it needs a violent contraction of his stomach to get rid of the airball, and thus causes regurgitation of food. In between meals, drinks of warm water help a baby to get rid of wind. Aerophagy is produced not by rapid intake, but by uneven sucking due to over-excitement and hunger; it is very usual. All excitement must be avoided when the baby is drinking.

ARTIFICIAL FEEDING.

Every baby is a law unto himself, and what will suit one child may not agree with another. The food next to human milk is modified cow's milk. Cow's milk is just right for the calf, but not for the baby, unless the milk is especially modified to fit it for the young human being. Cow's milk is much richer in protein than human milk, therefore it has to be diluted with boiled water or barley water. This dilution diminishes the fat and sugar, so more fat and sugar have to be added. When modifying cow's milk, the inorganic salts are reduced by dilution, hence the necessity for raw beef juice, which must be very carefully prepared. When baby has become used to modified milk, whey can be used instead of water. This will supply inorganic salt, vitamins, and milk sugar. No sugar need be added then.

Cow's milk must be sterilised—boiled for three minutes—brought to the boiling point rapidly, boiled three minutes, and cooled quickly. The germs of gastro-enteritis, summer diarrhoea, tuberculosis, or typhoid may be in the milk. Therefore it is best to sterilise it. To keep milk relatively germ-free is very difficult because it is a splendid medium for germs to flourish in, and they flourish and multiply if the milk is kept at average summer temperatures. So the first thing to remember is that even sterilised milk does not remain safe unless kept free from contamination and also kept very cold. The jug of milk should stand in a basin of cold water and be covered with a wet muslin or fine net cloth which covers the whole jug, dips well into the water, and placed in a cool safe or a good cool draught. Do not use a thermos flask to keep milk or any other food warm for baby. The prolonged warmth causes bacteria to multiply. Boiling of milk kills the harmful germs and also spoils the vitamins. To see that baby gets those vitamins which are essential to health, give him fruit juices. The fruit juices are orange juice, tomato juice, and grape juice. Orange juice is the best; because oranges are longer in the sun they mature more slowly than other fruit. The health-giving rays of the sun which impart vitamins to growing things impart to oranges Vitamin C, which is a preventive of scurvy. Give baby a little strained orange juice once every day; failing that, tomato or grape juice.

To make whey, take 18ozs. of milk in a saucepan, make it lukewarm, add one junket tablet, stand for three minutes, when a firm curd should have formed. Break the curd with a fork, put the saucepan on the fire and bring to the boil. Pour off the whey from the curd, straining it through a scrupulously clean boiled strainer. Whey made from new milk contains about one-third of the fat of the milk.

To make beef juice: Raw beef juice should be given to all weaned and to all artificially-fed babies, and continued until baby is 18 months old, when he will be able to take finely cut red meat. It is made by taking 2ozs. of juicy beefsteak and cutting and shredding it very finely with a very sharp knife. Then add a pinch of salt and 2 tablespoons of cold boiled water. Stand for two hours in a cool place, then mix it well with a spoon, squeezing and pressing it. Strain it through clean boiled muslin. Do not warm it; give it cold—this is very important. A baby will take this readily. To a very young baby give only a few drops at first once a day. Gradually increase the amount. At nine months give 1oz. a day. Great care in preparation is necessary. Have all utensils very clean. Strain very carefully so as not to get the smallest speck of meat in the juice. Make a fresh quantity every day.

WEANING.

Make all changes slowly. When changing a baby's food and when weaning a baby always dilute the food to give the baby time to learn to digest the new food. Commence with half and half. This can be altered day by day, by the increase of 1 tablespoon of the food and 1 tablespoon less of water until the food is undiluted. For babies being weaned under nine months of age, the best food is modified cow's milk. Babies of nine months can be weaned on to whole cow's milk. If weaning on to whole cow's milk, commence with half milk and half water, and gradually add more milk and less water. If weaning on to modified cow's milk make up half the quantity required for the drink and then make it up to the required amount with water. Gradually increase the strength of the drink. Nine months is the best age to commence weaning. At first give only one artificial meal a day. After a week, when the proportions of the artificial drink are four of the food (milk) and one of water, give two artificial meals a day. Increase the strength of these two meals gradually until they are undiluted. The best meal to make an artificial one at first is the 2 p.m. When giving two artificial meals change also the 6 p.m.

It is difficult to get a breast-fed baby of nine months to take a bottle, and it is better to wean him on to a cup and spoon. At first he will probably make a fuss, but the mother must persist, holding the baby with his head well back and putting

the food a little at a time into his mouth. After a week in which two artificial meals a day have been included, a baby will, as a rule, take his meal quite nicely. The next week a third meal can be made—an artificial one—namely, the 10 p.m. one. At this time commence orange juice. Give it between two meals (not too soon after a meal). At first give 1 teaspoon of strained orange juice diluted with 1 teaspoon of water. The amount and strength of the orange juice can usually be rapidly increased. Judge by the baby's bowel action how much to give. Cold raw beef juice—1oz.—should be given once a day at this stage.

After the baby has been having three artificial meals for a week, the fourth meal could be changed: that is, the 6 a.m. drink. Now he will be able to do without the fifth drink, the 10 p.m. one. The times of these four meals should be 6 a.m. and 10 p.m., 2 p.m. and 6 p.m. After this 6 p.m. drink he should be sponged and put to bed, and he should sleep through the night. If the baby has been weaned on to modified cow's milk, this can be gradually changed into cow's milk when he is nine months old.

At the age of six months baby can have a cleaned chicken or chop bone to suck. When he is seven months give him unbuttered rusks occasionally before a drink. Butter rusks and crusts for him at eight months. At nine and a half months he can have a little scraped apple. Do not add sugar to baby's milk. Gradually the baby is given more solid foods: eggs, potatoes, porridge, and vegetables are gradually added (in very small quantities at first), so that by the time he is one year old he is having a very nutritious diet, and three meals a day will be quite enough for him. With each of these three meals it is important for him to have from 8ozs. to 10ozs. of milk. This should be given in preference to other food. The milk should be drunk first. Glass beer mugs with handles and holding at least 10ozs., or half a pint, are very suitable for the children's milk. They are weighted at the bottom and do not easily fall over. At one year old the baby can have his meals at 7.30 a.m., 12.30 p.m., and 5.30 p.m. These times are convenient, for as he is spoonfed, it is best to feed him just before the family meal. As he gets older and more able to feed himself his meals should coincide with those of the family. This is rather important, as a child will take food more readily and enjoy it better in company. By 18 to 20 months of age most children are able to feed themselves. It is good to train the child to be independent. Do not allow him to play with his food or splash it about. Give drinks of water between all meals. At 10 months baby may have his crust dipped into a very lightly boiled egg, or he may have a little custard, boiled or baked, commencing with 3 teaspoons. The quantity of egg food should be gradually increased until by the age of 12 months baby can be given an egg a day. If a child is not fond of eggs he can be given half an egg only, sometimes missing it for one day, but it is important that all children over 12 months should have egg food each day in some form or other. For a baby an egg should be very lightly boiled and then beaten up with 2 teaspoons of bread crumbs. At 15 months baby may have fish or brains; at 17 months rabbit and chicken, and at 18 months red meat.

Suggested diet for healthy child of 12 months:—*On waking*: a drink of water (8ozs.). *Breakfast*: 7.30 a.m., 8-10ozs. milk, a little porridge, a buttered rusk, a little raw fruit. *Mid-morning*: Drink of water or orange drink (8ozs.). *Dinner*, 12.30 p.m.: 8 to 10 ozs. milk, 1oz. raw beef juice, 3 teaspoons well-mashed potato, 3 teaspoons well-mashed beans or peas, a bone to suck, a little raw fruit. *Mid-afternoon*: Water 8ozs. *Tea*, 5.30 p.m.: 8 to 10 ozs. milk, lightly boiled egg beaten up with 2 teaspoons of dried bread crumbs, buttered rusks or crusts and honey, a little raw fruit.

The most important food is milk, then follow meat, eggs, raw fruit, raw vegetables, and butter. Least important are the starchy foods and sugar. The starchy foods include potatoes, bread, biscuits, and all puddings with the exception of those made with eggs and milk.

Food is cooked to render it more digestible, but a diet of cooked food is not sufficient for health. It must contain some fresh raw food, such as raw fruit and raw vegetables (lettuce, celery, watercress).

VITAMINS.

There are certain life essentials in food, which have been called vitamins, and which have been classed as A, B, C, D, and E. Foods vary in the amount and nature of the vitamins they contain. Heat affects the value of vitamins. The greater the heat the greater their destruction. Heating rapidly does not affect them as much as a lower degree of heat continued for a long time. Cod liver oil is rich in Vitamins A and D. To obtain vitamins in plenty in our food we must eat a certain amount of raw food. Cod liver oil, being very rich in Vitamins A and D, is good for growing children, especially in winter.

Fish is a good food for all over 15 months. For babies break it down well and remove all bones. At 15 months baby may commence to have a teaspoon of this, then gradually increase the amount; let older children have steamed fish once a week instead of meat. If carefully and lightly cooked, brains are a good food. At 15 months a baby may commence to eat brains boiled (not fried), served with white sauce or in milk. Give 2 teaspoons once a week, gradually increasing the amount and frequency. The babies that have been taking fish and brains at 15 months may at about 17 months have a little well-cooked rabbit and chicken, and at 18 months a little finely-cut red meat from a grilled steak or chop. Commence with 1 teaspoon at first and very gradually increase the quantity. Children should have meat once a day only, and that at mid-day. Train them to eat a little fat with their meat. All meat should be well cooked, but not over-cooked. A joint should be put into a very hot oven, but soon after the heat must be reduced. A dish of water placed in the oven helps to prevent the meat from becoming too dry. Meats suitable for children are roast mutton, roast beef, roast chicken, grilled steak, grilled chop, stewed rabbit, well-stewed steak, well-boiled tripe, and well-boiled sheep's tongue.

FRUIT.

All kinds of raw fruits are good for health, especially oranges, apples, peaches, pears, and apricots. Fruit should be quite ripe, but not over-ripe. Cooked fruit is not so valuable. Raw fruit is rich in vitamins. It serves not only as a food, but where firm enough, gives the teeth good exercise in chewing. It also acts as a cleanser for the teeth; therefore give fruit last at each meal. Bananas are not suitable for young children through the swallowing of large pieces of banana without being chewed. When bananas are given they should be finely cut or pulped with a fork.

VEGETABLES.

Each householder would do well to have a vegetable plot in his own yard, and where possible a lemon tree. Raw vegetables, such as celery, watercress, and lettuce are better than cooked vegetables for all. Do not give raw vegetables to babies under 18 months of age. Great care is necessary in preparing raw vegetables. They should be well brushed and very thoroughly washed and then dried. The importance of washing well is immense. Threadworms may be acquired by eating raw lettuce not well washed. Potatoes are a starchy food, but nourishing. At 10 months baby may have potato well mashed, but do not add milk and butter, because they make potato indigestible. Commence with 2 teaspoons and gradually increase. Vegetable juice can be given to babies of any age. It is useful when fruit juice is unobtainable. Carrots and turnips are most suitable for this. Wash the vegetable well, plunge into boiling water for half a minute, scrape the skin off, and then grate it up. Just cover with cold boiled water and leave for two hours. Then strain through clean boiled muslin. Commence with 1 teaspoonful.

Butter is a most important food for children and should always be given freely, though not to excess, or it will act as a laxative and may cause indigestion. It is the main fat food in a child's diet. At eight months, baby may have butter on a rusk or a crust of bread. Give it just before a drink.

Pure wholemeal bread is rather difficult to obtain, but it is more nutritious than white bread. If given continually, children soon tire of it. Brown scones can be made of flour composed of half white and half pure whole wheatmeal flour. Make the dough fairly moist. They are delicious and a nice treat for children. Well-made toast and rusks buttered when cold should be given daily. Rusks are made by baking dry bread until it is golden brown in the oven. Do not give fresh bread to children. Encourage them to eat crusts.

Biscuits lend variety to food, but as a rule they have too much cane sugar in them and it is better not to give them at all to babies under one year old. Buttered wheatmeal and oatmeal biscuits and ginger nuts are very good for children over one year old.

Nuts are a splendid food but need to be pulped or chewed well or they pass through undigested. Do not give them to children before they are at least three years of age. Honey should be given freely to children of 10 months and over. It is an excellent food. It is generally well liked and sweetens the food without doing harm. Cane sugar taken in excess is distinctly harmful. All foods containing sugar should be given in restricted amounts. Portion out the number of lollies and biscuits and limit the quantity of cake, pudding, &c., and allow the children to eat their share only at their meals—never between meals, for they are always harmful then. Hard-boiled lollies are dangerous to young children. If one is swallowed whole it may lodge in the throat. Sticky lollies cling around the teeth and cause decay. Soft puddings cannot be recommended as a rule unless made of pure milk. Rice is a very good food. Sago and tapioca are poor starchy foods. Jelly in itself is useless as a food. It has no food value beyond the sugar or other food that has been added to it. Those containing milk and eggs, e.g., milk jelly and vanilla cream, are good.

FOODS TO BE AVOIDED.

Pepper, mustard, vinegar, and all condiments should never be given to children. Corned beef, sausages, pork, ham, bacon, sauces, pickles, all tinned foods, all highly-flavored and spiced foods, pastes, pastry, cucumber and radish; any food that has been soaked in fat is difficult to digest and should not be given to children—like hot buttered toast. Butter should not be put on hot vegetables. Casserole cooking is indigestible. Fatty acids permeate the food, rendering it highly flavored and very palatable, but at the same time indigestible, and therefore unsuitable for children. Cheese is a very good food for adults. Being a concentrated nourishment, only a little should be taken at a time. It is not suitable for children.

In dealing with fried foods, it is important that the frying be done properly so that the food is not soaked with fat. When dry-frying, first cover the food to be cooked in flour or in egg and breadcrumbs to prevent the fat from entering the food. Use very little fat; have the pan well greased all over and have it at a very high temperature before the food is put into it. The heat will immediately convert the coating into an envelope through which the fat cannot enter. Soon turn the food, and when both sides are lightly browned, lower the heat and cook slowly. Put a cover over the fryingpan to keep in the heat, and thus aid the cooking.

Wet-frying is different. Have a large quantity of fat in a deep vessel and submerge the food totally in the fat. This fat must be brought to the boil, 400deg. Fahr., and then the heat is raised yet higher until the bubbling fat is quite still again and a blue flame is noticed on the surface of the fat. Then the food is placed in the frying-basket, which is sunk in the fat until the food is quite covered. At this great heat no fat will enter the food, and the food will be well cooked. However, there is danger in using fat in quantity at such a high temperature. A drop of water accidentally splashed in would cause the fat to burst into flame.

MEALS.

Three meals a day are sufficient. There must be no food between meals. The digestive organs can then deal with one meal at a time with a rest between. This is very important if they are to function well. Children should have their hot dinner of meat and vegetables at mid-day. Avoid lunch at school if possible, but if circumstances render it necessary, make the lunch as nourishing as possible, including a bottle of milk and raw fruit. The more nourishing a diet the less required. It is important not to give a child too much to eat. Serve moderate amounts, and a little more can be given if desired. A mother can be guided by a child's appetite if a child has always been carefully and regularly fed at proper intervals. Give a dry diet that has to be well chewed and mixed with saliva. Avoid slop foods where possible. Soups and broths may stimulate the appetite, but should never be allowed to take the place of more important food. They consist of much water with a little extract of meat, &c., and are better omitted. The chewing of food is extremely important to the teeth. This is necessary to their wellbeing, for the movement stimulates the blood supply of the teeth, keeping them healthy. It also excites the secretion of digestive juices. Thorough mastication takes time, and therefore a proper amount of time must always be set aside for each meal. Food eaten quickly without being chewed does more harm than good. Undigested food may form poisons which are absorbed, and will probably give rise to headaches and to other symptoms of toxæmia or auto-intoxication—so-called bilious attacks.

Fluid can be taken either at mealtimes towards the end of the meal or between meals. Children should drink milk as part of their meals and only water between meals freely. Water drunk last thing at night will disturb sleep. Tea and coffee are harmful and unnecessary for children. They will not miss them if trained to do without. Soft drinks, such as lemonade, ginger beer, &c., are not good for children. All drinks containing alcohol: for example, wine, beer, whisky, brandy—must be forbidden absolutely.

Suggested meals for a young family two years and older:—

6 a.m.—Water 8ozs.

Breakfast, 8 a.m.—Milk $\frac{1}{2}$ pint (10ozs.); a little porridge, egg and toast, 1 apple.

11.30 a.m.—Mid-morning drink, water or lemon drink (8ozs.).

Dinner, 12.30—Meat, potatoes and green vegetables, junket (10ozs. milk), oatmeal or wheatmeal biscuits, and gingersnaps, a little raw fruit.

4 p.m.—Water 8ozs.

Tea, 5.30 p.m.—Milk $\frac{1}{2}$ pint (10ozs.), raw celery, lettuce, or tomato, rusks or brown bread, butter and honey or lemon cheese, a little raw fruit.

TOYS.

[MRS. F. CUMMINGS, Belalie.]

Before giving a demonstration of toys made in the home, it is proposed to relate how England provided toys for the children during the Great War. A lady who was visiting England during the War spent much of her leisure in toy-making, and has written the following article on the subject:—

“Previous to the Great War England imported most of her toys from Continental countries. The War broke out in August, 1914, before any Christmas orders had entered the country and there was a scarcity of toys in most of the smaller towns; consequently the English children were faced with a toyless Christmas.

Two kind-hearted elderly ladies of Devon formed a working party to make toys for the children's Christmas. Having plenty of leisure I joined the class, and soon found the work very interesting. At first only small soft toys were made: rabbits of various kinds—Mr. and Mrs. Peter Rabbit complete with basket of carrots and umbrella, the White Rabbits copied from “Alice in Wonderland,” Dogs, Elephants, Penguins, and Lambs.

As I was from Australia, our instructress insisted on the Kangaroo being added to the family, and he became a great favorite with the little English children. Dolls were also made—small black dolls, black golliwogs, and dolls made of two colors and dressed as Jesters.

Material for the toys was purchased in rolls—ripple flannelette for the animals, and calico and sateen for the dolls—while small pieces for dressing the dolls were given by friends and samples from the shops. The stuffing was more difficult to obtain, as wool, flock, and materials of that description were too scarce and costly. The difficulty was overcome by collecting straw packing and shavings from shops; also cork-dust in which grapes imported from Africa were packed. This answered very well, and large orders were received from London and other large towns. By the second Christmas dolls' heads and limbs were procured from a Staffordshire pottery. These were bought by the gross and attached to calico bodies; the wigs for the dolls came from a firm in Birmingham, and it was a work of art to select the wig most suited to the doll's complexion. Some wigs were curled, some straight, and many in two pigtales, either fair or dark and tied with colored bows. Each assistant had her own job; mine was cutting and stitching; another did the stuffing, someone else the finishing, and so on. A young girl about 17 did most of the designing. The children often came to watch the toys being made, among them many Belgian refugees. It was not unusual for the small folk to request that their doll be dressed as a soldier or a nurse. The character dolls were always favorites. "Jig-saw" puzzles were made for the older children. Tea boxes were procured from the stores; the wood from these smoothed with emery paper, pictures pasted on and then sawn into pieces with a fretsaw. These were done up in fancy bags made from scraps of material. Although the business was so successful, the toys were sold so cheaply that only enough money was made to defray expenses—hire of room, cost of materials, &c. I worked in the toyshop for three years, giving most of my leisure time until at the close of the War I returned to Australia. Ours was only one of the many toy-shops organised by the lovers of children in larger towns of England during the War."

HOME-MADE TOYS.

Toys are so cheap now that it would not pay to buy new materials to make them, but old garments and scraps from the patch bag can be used to make nice toys to gladden the hearts of many poor children whose parents have not the means to purchase toys for Christmas stockings. The toys exhibited were all made from old garments, pieces left over from dressmaking, odd balls of wool, a little colored silk, and a few buttons.

Priscilla the Penguin was made from some scraps of velvet and stuffed with flock. *Dilly the Duck* is big and soft and will serve as a pillow when baby falls asleep at play. Her grey covering was only a flannel under-garment. A few scraps of flannel made gay feathers for her wings. She swims on the carpet. *Koala the Bear* is part of an old winter's coat with a scrap of brown velvet for ears. He is filled with flock and is altogether a quaint little chap. *Mr. Roo* is stuffed with straw packing and his coat was a piece left over from a small child's winter outfit. As the pattern was designed by an English girl he looks as though he might be a distant cousin to our kangaroo. *Fido* is also made from an old winter coat and filled with straw packing. *Mr. and Mrs. Peter Rabbit* are soft and cuddly, filled with wool, and quite smart in their best clothes. *Golliwogs* may be knitted from odd balls of wool left over from jumpers, &c. *Sambo* is an old woollen stocking, as also is the little black *Kitten*. Quite a small child can cuddle them. *Jumbo the Elephant* has a nice grey coat which one would not recognise as being the best parts of an old discarded pair of moleskin trousers; his gay trimmings make him a great favorite with small children. The woollen balls and rattles are for the tiny tots and may be hung on the perambulator for baby to play with. At Christmas poor children in big towns will appreciate any of these toys, and besides giving pleasure we have the satisfaction of making something from nothing.

GOOD FELLOWSHIP.

[MRS. A. E. PAGE, Belalie.]

A notable example of fellowship in modern times is the Returned Soldiers and Sailors League, whose members are joined by the common link of having been comrades in arms during the Great War. Man is a social being, and the ground of fellowship is our common humanity. The social instinct is bound up with the constitution of our being, and has been implanted therein by the Creator. The oldest record of the race tells us that at the dawn of humanity the Lord God said: "It is not good that man should be alone," and mankind was thus grouped in families, clans, and communities. In the course of time these units were extended into larger groups, and thus the great nations of the earth came into existence.

But the fellowship of the human race was not always "Good Fellowship," and the early annals of our race are marked by wars, strike, and bloodshed. Advocates of the scientific theory of evolution claim to see in these upheavals the process of the elevation of the race by means of the "survival of the fittest," but one cannot avoid the feeling that the highest destinies of the human race are to be promoted by the exercise of good fellowship and peace. There can be but little doubt that the conditions of modern life are most favorable to bringing people together in closer union and fellowship. For one thing, there is a far swifter means of communication between country and country than existed a century ago.

The early pioneers of the State who left the shores of their native land no doubt felt that they were going away into another world, so little means of communion had they with the land and friends which they left behind. But the introduction of swifter means of travel, and a better means of communication, have brought the distant countries nearer to one another. The marvellous inventions of air travel and the wireless have been the cause of removing the barriers of distance in a manner undreamed of by our fathers. These two inventions have been of special benefit when applied to the open spaces of the vast island continent of Australia. In former times we were appalled by the extreme loneliness of the people who lived in the far inland portions of Australia. Such conditions rendered it almost impossible for families to be reared in these far remote districts, but thanks largely to the efforts of the Australian Inland Mission, the establishment of the wireless stations, and the "Flying Doctor," have brought the benefits of civilisation within reach of the most remote. Perhaps the sense of how wonderfully near we are being brought into touch with others has brought home to a number of the most thoughtful people the great need for the cultivation of the spirit of good fellowship. The almost world-wide depression through which we are passing emphasises the need for the cultivation of the spirit of good fellowship, for if we are to soften the pain and disappointment of unemployment and poverty, we can only do so by the exercise of the spirit of comradeship and goodwill.

Who is there who has travelled to any extent in a public conveyance who has not experienced the pleasure that can be derived from social companionship. The distance has often been materially shortened, in imagination at least, by social conversation with folk one has never seen before and in all probability will never see again. Fellow-passengers on railway or steamer live for a time at least in a little world of their own, and are like "Ships that pass in the night." Surely it is worth while to afford some pleasure to these brief wayfarers, especially if the pleasure of comradeship is mutual. There are, of course, certain restrictions and social barriers in the way of these passing fellowships, but these barriers are far less than one would suppose.

This affable and friendly spirit is characteristic of the true nobility and titled class of the old land. I am inclined to believe from all that I have read of the Feudal System, that the knightly vow enjoined upon the one who had taken it the strictest courtesy and kindness towards all, whatever their rank or station may

have been. Chaucer in his "Canterbury Tales" gives a description of the Knight who travelled in the company of the pilgrims, and amongst his many excellencies he added that he had never been known to speak a harsh or unkindly word to any person of whatever rank they may have been. And if the spirit of good fellowship can bridge the barrier of social class, it surely should be able to pass over the barrier of race, of nation, and of color. In Australia we have need for thankfulness that we have never been seriously faced by the "color problem." In South Africa and in the United States of America the color prejudice has been most intense, and the infusion of colored blood, however remote, acts as a barrier which is well nigh impassable. Nevertheless, we should never forget that in Australia there are still many thousands of full-blooded natives living. These people were the original dwellers in our land, and as such they constitute the true aristocracy of Australia. In her book, "The Australian Aboriginal as a Human Being," Mrs. Bennett reminds us that the early white settlers made no effort to treat the blacks kindly, but massacred and ill-treated them shockingly. She writes of them as the most interesting race in the world, and the most wronged at our hands, and all who read without bias the history of our failure in the past to protect and help the native must indeed feel a debt of gratitude to this brave woman who has so fearlessly upheld their cause, and is counting not the cost if she can help to bring about a system that is equally just to the black as well as the white citizen of Australia. Mrs. Bennett gained much practical knowledge of the aborigine through association with them in North Queensland. Her sympathies were aroused as she recognised the intelligence and loyalty which is a characteristic of this dark race. She has also been successful in arousing some of the leaders of Women's organisations in Perth to a greater sense of their responsibility in relation to the lot of their dark sisters.

It has also been proved that the aborigine woman can be taught useful and skilful arts, for Mrs. Bennett has visited some of the Mission centres with her spinning

wheel, with the result that in these Missions the women are now spinning and weaving cloth for garments. " " "

The cultivation of the spirit of comradeship is by no means easy, for we are called upon to overcome our natural diffidence; but the effort required is more than repaid by the pleasure which comes not only to others but to ourselves. There are many people with whom we come in contact who are warm-hearted and companionable, if only we could break down the barriers of reserve, and in order to win their confidence one is called upon to exercise the most friendly and sociable spirit. Good fellowship means refraining from conduct of an actively unsociable character. But opportunities for good fellowship to-day are wide and varied, and surely there is no one who cannot find some means of exercising it, not for our own pleasure only, but to make a contribution to the wellbeing of others.

Life is too short to waste, and there is an obligation resting on each one to see to it that our fellowship with others is uplifting. We all associate with people of very different temperaments. Is it not true that sometimes we feel depressed in spirit after being in the company of some people, while on the contrary, after being with others we are always cheerful. True fellowship is only possible where there is high ideals, and if our motto is "The utmost for the highest," we shall endeavor to lift the things about us on to a higher level, and make this world of ours a better and sweeter place.

PAPERS READ AT CONFERENCES OF LOWER SOUTH-EAST BRANCHES.

There was an excellent attendance of delegates from the Penola, Millicent, Kalangadoo, Rendelsham, and Tantanoola Branches, as well as a large number of visitors at the Conference held at Tantanoola on April 11th. Mrs. D. Considine presided, and the following papers were read and discussed:—

PRESERVING FRUITS.

[Mrs. H. A. RESCHKE (Coonawarra.)]

A valuable asset in the home for winter and early spring is a good supply of preserved fruits. When fresh fruits are not available, and to have this supply on hand, it is necessary to preserve each kind of fruit as it ripens. Fowler's preserving outfit and bottles are the best, but Mason jars can be used in the Fowler's preserver as well. If Mason jars are used fill tightly with the aid of the packing stick. Add water as syrup; put on the rubber ring, which has been scalded first in boiling water, then the lid, which has been scalded also, and screw down lightly. If they are screwed very tightly the jars sometimes crack off just under the lid. Put into a steriliser, and sterilise as directed for each fruit. When taken out of the steriliser, screw down as tightly as possible with the wrench used for Mason jars. In selecting fruits for preserving, use at the exact ripeness, if possible—ripe enough to have the nice flavor of each fruit, and not too green or over-ripe. Fruit over-ripe will never be a great success; it is likely to squash when filling the jars, and rises very quickly in the bottle. Always fill the jars tightly with fruit; this also helps to keep it from rising in the jars. Cherries and gooseberries are about the first fruits to ripen; they preserve well. Apricots come early in the new year, and are one of the best fruits to preserve, Moorpark being the best variety to use. Cut the apricots in halves, take out the stone, and pack well in layers, one piece over the other, with the cut side downwards. Fill up the bottles that way; put in the syrup, and fill to the top. Put on the rubber ring, which has been previously scalded, then lid, also scalded, and press the lid down. See that the ring does not bulge over the lid; put on clip, and place in the steriliser. Continue until the steriliser is full; then put water in the steriliser until it is three-quarters of the way up the bottles. Put the

steriliser on the stove, and bring the temperature slowly up to 160 degrees, and maintain as near as possible for 1½ hours. Mulberries are a great stand-by during winter to use with apples as conserve, or for pies. Fill the jars as full as possible, crushing the mulberries down, and preserve them in their own juice, without water or sugar. They have the true mulberry flavor when opened, and the sugar can be added as they are mixed with the apple. They can also be preserved with sliced apple or quince. They require exactly the same temperature as apricots, slowly bringing up to 160°, and maintaining as near as possible for 2½ hours, instead of 1½, as for apricots. Nectarines can be packed exactly the same as apricots, and bring slowly up to 180° in temperature, and maintain as near as possible for ½ an hour only.

Nectarines are very sensitive to heat, and rise in the bottle if the temperature comes up too quickly. Pears are one of the best fruits to preserve, and are easily done, but the temperature is higher than most fruits, being 200°, allowing to drop to 180°, and maintaining at that for 2½ hours. Prunes and plums are easily done, preserve well, make a nice collection in the pantry, and are very useful in the home.

Tomatoes are easily preserved, and are a great success, either whole or pulped. Peel and pulp them, and do not use either water or salt, only their own juice; and they make delicious tomato soup in winter. Mushrooms are also very good. Peel and clean the mushrooms while quite fresh, and place in a saucepan, with a little butter, pepper, and salt, and boil very slowly, and cook them in their own juice instead of using water. When cooked allow to cool, and then place them in bottles, and preserve as directed in Fowler's book. They must be sterilised twice, or they are likely to ferment. They can then be used at any time of the year, and make delightful breakfast dishes if heated and placed on toast.

HOUSEHOLD ECONOMIES.

[Mesdames EDGCUMBE and BURCHARD (Tantanoola.)]

In the successful management of the home it is essential to economise, mainly by using, whenever possible, products of the farm in preference to goods purchased from stores, and to avoid wasting anything that could, perhaps with a little extra trouble or cost, be made into something both practical and useful.

Where meat is killed on the farm there is usually sufficient fat to provide the dripping for cooking purposes, and tallow for soaps and candles.

Economical Household Soap.—7lbs. clean fat, 1lb. washing soda, 1 tin caustic soda, ½lb. resin, 2½galls. water. Boil an hour.

Sand Soap.—Cut up 1 bar of household soap in a cut kerosene tin, with a quart of water. Stir over fire until soap dissolves. Then add 1 quart of clean white fine beach sand and 1 quart of white wood ashes. Remove from fire, and stir occasionally until it begins to thicken. Turn into mould, or cut into blocks when cold.

Oatmeal Toilet Soap.—To each ½ cup of scraps of household soap add 1 cup of hot water. Dissolve, and, while slowly boiling, stir in sufficient fine oatmeal to form a firm mixture. Scent may be added. Pour into mould.

Tallow Candles.—Dissolve 1 dessertspoonful of alum and 1 dessertspoonful of resin (powdered) in melted tallow—1½ pints for 6 candles. Thread mould with wick previously dipped in kerosene.

Simple Home-Made Disinfectants (for Washing Floors).—Take 1 bar of ordinary soap, and dissolve in 1 quart of water, with 1 bottle of Solypol and ½ pint of turpentine. Boil all together, and put in a tin. A tablespoon in a bucket of water is sufficient to refresh a room.

Useful Mop Oil.—1 cup raw linseed oil, 2 cups kerosene; shake well together.

Preventive for Dandruff (good for school children).—1 part kerosene, 2 parts olive oil; rub well into the scalp.

Anchovy Mince.—Cut 1lb. of steak into small pieces, put in a jar with ½lb. butter, a little mace, pepper and salt. Cover closely, and stand in a saucepan of water,

and simmer 3 hours. Drain off gravy, and mince the stock. Add to it the gravy with 1 tablespoon of anchovy sauce and a little nutmeg. Beat all together; place in jars. Excellent for sandwiches.

Flour Paste for Jams, &c.—A good recipe that will keep. Sift 1lb. of flour, and stir in about 1½ pints of water, or till the mixture is like a thin cream. Place over a slow fire, and bring slowly to the boil. When boiling, add ½oz. each powdered alum and boracic. Stir constantly while cooking, and boil 5 minutes, or longer if possible. Allow to cool, and add 1 teaspoon of oil of cloves. Pour in small pots, and seal down.

Baking Powder.—½lb. ground rice, 4ozs. carbonate soda, 3ozs. tartaric acid; roll out all lumps; sift twice, and store in airtight tins.

Self-Raising Flour.—24lbs. flour, 18ozs. cream tartar, 9ozs. carbonate soda, 3 dessertspoons salt; rub lumps from carbonate soda, mix with flour, sieve through fine sieve several times, and keep in airtight tin.

Cleanser for Canvas Shoes.—1 cup of boiled starch (thin), a squeeze of the blue bag, 2 tablespoons methylated spirits, enough whiting to make a nice paste.

Furniture Polish.—Equal parts raw linseed oil, turpentine, methylated spirits, and vinegar; mix well. Put on with a soft glove, and rub up with same.

Dried Apples and Pears.—When the fruit crop is heavy peel and slice, spread on a large frame with small mesh wirenetting in the sun to dry. Store unbleached calico bags, and hang in draught.

To Prevent Table Salt from Going Lumpy.—To every 1lb. of salt add 3ozs. of corn-flour; sift 3 times. The product is very nice, keeps dry, and may hardly be distinguished in appearance from shaker salt.

For Rough Hands.—Equal parts of lemon juice and glycerine; put on hands while damp. The same mixture is excellent if taken for an irritating cough.

To Get Rid of Ants.—Moisten with water a mixture of borax and sugar. Place in lids of a tin where the ants are troublesome.

Glaze for Pastry.—A different and delicious glaze for pastry can be made by using the syrup of apricot jam. Thin with hot water, and apply with pastry brush as soon as the pastry is taken from the oven.

To Make Lime Water.—Dissolve a lump of unslaked lime (about 1 dessertspoon) in 1 pint of waetr. Next day pour off clear liquid. Useful for burns if equal parts of lime water and oil are mixed to make carron oil.

A Use for Old Wool.—A cosy rug may be made from old skein wool by crocheting loops around the finger, giving a looped appearance to the finished article.

Sugar Bags can be utilised for various useful articles—work aprons, laundry aprons with waterproof slip, verandah cushion covers, peg aprons, &c.

Floor Cushions (from tins).—Procure any kind of tin. For each cushion the tins must be alike. To make a nice size cushion take 7.2lb. treacle tins; another nice shape is with 9 honey, health saline, or coffee tins. The following material is required:—The one piece, or different scraps; 2 pieces cardboard and wadding for padding. Cover the centre tin with any old piece of material. Cover all other tins with material to be used, leaving 1in. longer top and bottom to turn in. Place tins together for the desired shape, and sew across; turn upside down and do the same. Place shape on cardboard, and cut out 2 pieces. Cover with material, place one on bottom of tins. Put padding on top; leave plenty of material to turn in on top of cardboard. Having completed this, sew some cord to match around the tins on the top.

MAKING DAINTIES FOR A CHILDREN'S PARTY.

[Miss JESSIE TELFER (Tantanoola).]

First, see that the oven is properly cleaned out at the bottom, and the shelves washed and dried. There must also be plenty of small wood ready. The oven must be kept at an even temperature; some require a quick oven, such as shortbread creams; others a very slow oven, such as rice bubbles and macaroons.

Shortbread Creams.—10ozs. flour, 5ozs. each sugar and butter, 1 egg, 1 teaspoon baking soda, 2 teaspoons cream tartar. Beat butter and sugar, then eggs; add other ingredients, and put through biscuit forcers. Bake in a moderate oven.

Walnut Fingers.— $\frac{1}{2}$ lb. butter, 2 ozs. sugar, $\frac{1}{2}$ lb. flour, 1 teaspoon cream tartar, $\frac{1}{2}$ teaspoon soda, yolk of 1 egg, essence of vanilla, warm water. Cream butter and sugar, add egg, flour, enough warm water to mix into a stiff paste; roll out, and spread with icing made from the white of 1 egg, and about $\frac{1}{2}$ lb. icing sugar. Flavor with essence of vanilla. Scatter chopped walnuts, and cut into fingers. Bake in a moderate oven.

Melting Moments.—8ozs. butter, 2ozs. cornflour, 6ozs. flour, 2ozs. icing sugar; mix butter and sugar, add flour, and drop on a slide.

Bird's Nests.—4ozs. each butter and sugar, 1 egg, 8ozs. self-raising flour, $\frac{1}{2}$ teaspoon ground cinnamon, a little apricot jam. Cream butter and sugar, add egg, then flour, &c. Roll out about $\frac{1}{4}$ in. thick. Cut into rounds; out of half the rounds cut the centres, leaving rings about $\frac{1}{4}$ in. wide. Bake in a moderate oven. Place a ring-piece on each biscuit after coating the whole with warmed apricot jam. Ice with chocolate icing, and sprinkle with brown coconut. Fill each nest with tiny marzipan eggs, made as follows:—Mix 2ozs. icing sugar and 2ozs. ground almonds, with a little yolk. Form into eggs, and leave to dry before putting into nest.

Peanut Crisps.— $\frac{1}{2}$ lb. butter, 1 cup of sugar, 1 egg, 1 cup of flour, $\frac{1}{2}$ teaspoon salt, 1 teaspoon cocoa, $\frac{1}{2}$ lb. raw shelled peanuts. Mix sugar with melted butter; add beaten egg and dry ingredients. Put dessertspoon on a buttered tray. Bake slowly.

Ujarganappy.— $\frac{1}{2}$ cup melted butter, $\frac{1}{2}$ cup sugar, 1 egg, 1 cup coconut, 5 small cups cornflakes. Beat butter and sugar together, add egg; then add coconut, and mix well with cornflakes. Use fairly hot oven, baking in cake containers.

Rice Bubble Macaroons.—2 egg whites, cup of sugar, $\frac{1}{2}$ teaspoon vanilla, 1 cup coconut, 2 cups rice bubbles, $\frac{1}{2}$ cup shelled nuts (chopped). Beat egg whites until stiff, add sugar gradually; then add vanilla, coconut, rice bubbles and nuts. Drop by spoonful on a buttered pan, and bake in a moderate oven until a delicate brown.

Sandwiches.—Take 5 thin slices of bread; spread thinly with butter. Spread first slice with curried egg, place a slice of bread on top, and butter other side, and then spread with cheese paste. Place another slice on top, and spread with butter and anchovy paste. Place another slice of bread on top, and spread with butter and ham paste. Place the fifth slice of bread on top and cut off all the crusts and cut into finger lengths. These are delicious.

MAKING AND WATERPROOFING OVERCOATS.

[Mrs. G. W. ALTSCHWAGER (Tantanoola.)]

I have been using these coats now for the last four years. They wear well, and are quite waterproof, and I can recommend them. Each year I oil them afresh, and, with care, they last for years. These coats are very easily made if one has an old coat pattern. I obtain a fairly good unbleached calico, about 1s. 5d. a yard, and wash the calico first, press it out, and then cut and make the coat to fit the girl or boy, as required. Double-line the yoke and the top of the shoulders to make the coat much stronger.

When the coat is made I purchase $\frac{1}{2}$ gall. of raw linseed oil; make it lukewarm in a flat dish, and put the coat in, and squeeze the coat well through the oil. When done enough take out, roll up in a ball for about 3 hours, and then take out and put a stick right through both sleeves. Hang up to drip, having a dish underneath to catch the oil. When it has finished dripping, warm oil again, with a little fresh oil added; dip coat again, and hang up as before. This has to be done three times, but only roll up in a ball the first time.

Leggings and caps that are a great asset can also be made. They cover the whole leg down to the instep; the child does not get wet, and the leggings keep the legs

warm on cold days. Put a tag on the top to fasten them on to the braces. They are also splendid for men for riding. I made 3 coats, which cost 15s. complete. These coats have lasted 4 years, with 1 oiling each year.

Top-Dressing for Coats.—1 small tin of black enamel, as much boiled oil as black enamel, ½oz. beeswax. Mix together, and heat over fire until wax has dissolved. Mix well, and put on with brush while hot.

DEYING FRUIT.

[Mrs. W. L. REDMAN (Penola.)]

The drying of fruit for home use requires no expensive outlay for utensils, etc., and is so simple that there should be no fruit go to waste in the home garden. The general principle involved is the removal by evaporation without injury to the fruit of sufficient moisture to ensure its preservation. The moisture may be driven off by exposure to the sun's rays or artificial heat. Trays of a convenient size may be made from match lining. Fairly effective drying may be done indoors in the stove, leaving the door partly open. Some varieties are dried whole, including grapes, prunes, figs, &c., which are usually dipped in a boiling solution of lye, which cuts the bloom and causes minute cracks to open on the skin, through which the moisture escapes more readily, thus hastening the drying process.

Apricots.—This fruit dries better and quicker if cut in halves and placed in a sulphur box. This process is carried out by placing the trays of fruit in a box the length and width to admit the trays being slipped in and out readily. Sulphur is then placed in a suitable receptacle, ignited, placed under the tray, and the door of the box closed. We usually leave it in all night. If the skin peels off easily it has had sufficient sulphur. The trays are then placed in the sun. The period required for drying depends on weather conditions, varying from 2½ to 4 days, or longer. When sufficiently dry the fruit should be pliable; yet when twisted between the fingers have no sign of juice.

Apples.—These are peeled, cored and sliced, dropped into a salt solution (about 2 tablespoons to 1 gallon of water, left for a few minutes, and sulphured for a few minutes.

Dipping.—The lye solution is made by dissolving 1lb. of caustic soda in 20galls. of water. An ordinary copper is suitable for dipping. A wire basket or perforated tin is necessary to hold the fruit during the dipping operation. Immerse the fruit into the boiling lye and count 30, which should be long enough to make minute cracks on the fruit. Prunes and plums are treated thus. Light-colored plums are improved if placed in the sulphur box.

Peaches are treated in the same way as apricots, but take longer to dry.

Pears.—Williams's Bon Chretien, better known as Duchess, are a good drying variety. They are cut in halves, the core removed, spread on trays, well sulphured, and put out to dry in the sun for the first day or two. After that they are stacked and allowed to dry in the stack. When finished they should be somewhat doughy and "stretchy" in texture if worked between the fingers.

SAVORIES FOR BREAKFAST AND LUNCHEON.

[Mrs. O. P. KLEMM (Rendelsham.)]

A good housewife can produce tasty and inexpensive dishes, made from "left-overs," with the addition of a little extra preparation, and one is only too glad, at present incomes, to make the most of simple, ordinary foods.

Regarding the extra preparations, say, for breakfast, much can be done the day before, such as mincing meats, preparing vegetables, or crumbling bread. Always save any gravy that is left from roast dinners, for, besides being helpful in serving

rissoles, patties, etc., it is useful to bind same. Eggs have excellent food value, but instead of having plain eggs and bacon, scrambled eggs, or boiled, every other morning, try to vary the menu by using them in some of the following ways:—

Eggs Poached in Tomato Sauce.—4 eggs, 4 rounds buttered toast, $\frac{1}{2}$ pint tomato sauce, pepper and salt. Put sauce in frying pan, and when boiling break eggs in and poach, basting well with sauce. Place eggs on buttered toast, and pour sauce over and serve, or the sauce may be kept for another occasion.

Eggs with Cheese Sauce.—Take 4 hard-boiled eggs, shell and cut in halves and put in dish, cut side up. For the sauce: Melt 1oz. butter in saucepan, add 1oz. flour, cook without browning, then add $\frac{1}{2}$ pint milk, and stir until boiling. Add 2ozs. grated cheese, pepper and salt, and pour over eggs. Sprinkle with a little grated cheese and serve very hot.

Moulded Eggs with Cheese.—3 eggs, 3 cups milk, $\frac{1}{2}$ cup grated cheese. Beat milk and eggs, add cheese and seasoning, pour mixture into greased mould and bake until brown and firm, turn out and garnish with chopped parsley.

Curried Egg Toast.—3 eggs, 1 teaspoon curry powder, salt and pepper, toast. Butter slices of toast and keep hot; beat eggs well with curry powder and seasoning. Heat a little butter in a pan, then pour in eggs. Stir over the fire until thick and set, but do not dry eggs by over-cooking. Pile on slices of toast and serve immediately.

Nest Eggs.—1 $\frac{1}{2}$ lbs. mashed potatoes, 2 tablespoons milk, 2ozs. butter, pepper and salt, eggs. Make the potatoes hot, add butter, milk and seasoning. Form in round shape with spoon on hot baking dish. Break an egg into each and bake in hot oven until set. Serve hot.

Tomato Toast.—Chop up a little bacon and put into small saucepan to cook with a small piece of butter, for a few minutes. Add 2 or 3 tomatoes (skinned and cut up) and add a little pepper. When tomatoes are well cooked break in 2 eggs and stir well. When thick enough serve on pieces of buttered toast.

Tomato and Cheese Savory.—Cut some fairly thick slices of cheese and cover the bottom of small flat dish with them. Take six small tomatoes, skin and halve them, then arrange over cheese, season with pepper and salt. Set tiny dots of butter on top of each tomato. Sprinkle with bread crumbs, bake in hot oven until light brown and serve very hot.

Potato Puffs.—1lb. cold mashed potatoes, 1lb. flour, $\frac{1}{2}$ lb. butter, a little salt and sufficient water to make stiff paste. Turn out on board and work well. Roll out thinly and cut in rounds as for pasties. Take a little cold meat (minced and seasoned) and place in each piece of paste. Fold over, press edges together, fry in pan half full of boiling fat. Cook on each side till light brown—about 5 minutes.

Meat Fritters.—Mince cold beef or mutton (or even rabbit), season it and flavor with mixed herbs. Make a batter with 2 eggs well beaten and pinch salt, 4ozs. S.R. flour, add little milk. Stir the meat into batter very lightly, drop into pan of very hot fat, taking large spoon for each fritter and fry until golden brown.

Another meat dish is cold meat and mashed potatoes blended with gravy or sauce; form into rissoles, roll in egg and bread crumbs and fry. Serve with gravy.

Potato Savory.—Grate 2 large potatoes, beat in 2 eggs, add pepper and salt, drop in spoonful of hot fat. Served with tomato or Worcestershire sauce.

To keep patties, &c., hot without becoming "soggy," a good plan is to have a wire gauze tray to stand over a baking dish, and the patties drain some of the greasiness away.

A Meatless Luncheon Dish.—Cut up 3 or 4 large onions and boil until tender. Grate 2ozs. of cheese and add to onions. Thicken with cornflour and serve on toast.

Parsnip Fritters.—Boil parsnips whole until cooked, but not too soft. Then cut in rings $\frac{1}{4}$ in. thick. Dip them in batter and fry in hot fat, drain and serve with chops or on toast. Carrots can be done the same, only add parsley to the batter.

Peeled Mushrooms on Toast.—Remove ends from mushrooms and clean, washing carefully in cold water, drain, place in pan with a little butter, season with salt and

pepper; cook 10 minutes, stirring lightly over fire, add a little chopped parsley and lemon juice; serve on toast.

Mushrooms with Onions.—Cut up onion and simmer in saucepan with a little water. When slightly cooked add sliced up mushrooms and simmer until tender, adding pepper and salt. Cover with milk and when boiling thicken with flour or cornflour and serve on toast.

Mince and Poached Eggs.—Place minced cold meat, pepper and salt, a little chopped shallot, and 1 tablespoon tomato sauce in a saucepan. Simmer gently without stirring much. Thicken with flour and place a flat layer on buttered toast, then a poached egg on each layer and serve hot.

An Easy Dish to Prepare.—Cut up some cold meat with an onion, put into a saucepan and cook with 1 tablespoon of butter until onion is tender. Cover with milk, let come to the boil, and thicken with cornflour, pepper and salt to taste. Serve on buttered toast. Fried tomatoes as a garnish improves the flavor.

Mutton Loaf.—2 cups each cold mutton and breadcrumbs, 2 eggs, $\frac{1}{2}$ an onion, pepper and salt, milk, tomato sauce. Mince the meat, soak breadcrumbs in milk, squeeze fairly dry and add to meat, then add eggs, well beaten, pepper and salt and minced onion. Press into well greased mould, cover with greased paper and steam 2 hours. Turn out and serve with tomato sauce.

Salmon Moulds.— $\frac{1}{2}$ lb. tinned salmon, $\frac{1}{2}$ cup hot water, 2 dessertspoons gelatine, 1 teaspoon finely chopped parsley, juice of 1 lemon, pepper and salt, 1 teaspoon good mayonnaise or salad dressing (may be omitted). Free the salmon from skin and bone, flake the fish finely, mix in parsley, lemon juice and seasoning. Dissolve gelatine in hot water and pour over other ingredients. Stir well and pour into small tumblers or cups to set. A slice of hard-boiled egg placed on top of each mould before it sets makes it even more appetising.

Tomato Jellies.—Simmer together $\frac{1}{2}$ lb. tomatoes, 1 small onion, 1 or 2 sticks celery, 1 teaspoon each vinegar and sugar, $\frac{1}{2}$ teaspoon salt, 1 clove, $\frac{1}{2}$ hour. Add dessertspoon gelatine, and stir until dissolved, strain the mixture through a sieve; when cool, pour in small vessels to set. Include in the lunch a few crisp lettuce leaves to be eaten with the jelly, or egg and lettuce sandwiches are equally good with it.

Sardine Eggs.—Boil as many eggs as required, shell and cut in half, and remove yolks. Scrape and bone 1 sardine to each egg. Pound yolks and sardines together, adding salt and a little cayenne pepper. Fill egg cases with a little of the mixture, shaving off a little at the bottom so that they will stand.

PRESERVED AND SMOKED FISH.

[Mrs. S. S. SMITH, Rendelsham.]

Fish, in order to be enjoyed, must be perfectly fresh. Sweep are very good keepers, and if to be kept a day or so should be sprinkled lightly with salt and pepper and hung in a cool, airy safe.

Frying is the most popular method of serving fish. They are also very nice stuffed with any good seasoned stuffing and baked in a hot oven. In order to fry fish satisfactorily, some little preparation is needed. Fillet the fish and then cut in nice pieces, not too thick, and roll in S.R. flour (with pepper and salt added), then dip in beaten egg and roll in flour again, and have fat at a high temperature and fry quickly. They have a nice, golden crust if done by this method and all the juices are retained. Another popular way is to dip in beaten egg and roll in baked and sifted breadcrumbs. Schnapper are particularly nice done this way.

A large sweep or schnapper, stuffed and then rolled in egg and flour and baked in a hot oven, served with either baked or mashed potatoes, makes a very nice meal and is much appreciated for a change.

A very successful way to keep fish on hand is to smoke or cure them. I have very good success with the following method:—First take out the backbone and have the fish in two large slabs, and then place in brine for 12 hours, remove from brine, rinse in clean water, and hang up to dry for a few minutes, then paint over with “essence of smoke” (a preparation on the market for the purpose), or, equally as good, smoke with wood smoke in old chimney if no smoke-box is available and when smoked sufficiently hang each piece separate in the safe. When needed for use, soak pieces of fish in a large dish of clean cold water overnight, and place fish in fresh cold water and bring to the boil, then simmer for about 15 minutes. This is very nice eaten with mustard sauce. Method to make:—1 teaspoon mustard, 1 dessertspoon each butter and cornflour mixed to a paste with milk, add boiling water until right consistency.

CRAYFISH.

The usual method of cooking is to boil in sea water, but if cooked at home they need plenty of salt added to the water in which they are to be cooked. About 20 minutes is the usual time allotted to their cooking, and when taken from water they should be immediately plunged into fresh cold water, which gives them a clear red color. Crayfish are very nice eaten cold with lettuce or tomato salad or mayonnaise dressing. Curried crayfish is very nice by way of a change. *Method to Make.*—Prepare curry by mixing 1 small dessertspoon curry with 1 tablespoon cornflour, 1 dessertspoon butter, small cup of milk, bring slowly to the boil and place in slices of cold crayfish and simmer for a few minutes. Serve on rounds of buttered toast.

Preserving Crayfish.—Take out of shell when cold and cut in neat slices and arrange with claws neatly in Mason or preserving jars. Put equal quantities of vinegar and water on to boil, add spices to taste. I use about 1 teaspoon of allspice and a shake of pepper, sugar and salt to taste; when cool, pour vinegar on to bottled cray and then seal and sterilise in the usual way. Screw down very tightly. They must be perfectly airtight or they will not keep. A very nice sandwich filling can be made by mincing cray very finely and placing in a saucepan with equal parts vinegar and melted butter, pepper and salt to taste. Simmer gently for a few minutes and pour into small jars and when cool pour fresh melted butter on top and cover with butter paper. This paste will keep for several days and is much appreciated by children in sandwiches.

RECIPES SUPPLIED BY PENOLA WOMEN'S BRANCH.

Apple Pulp.—Pare, core, and cut up apples, to every pound add 1 cup of water. Boil well without sugar, add $\frac{1}{2}$ lb. sugar to every pound of fruit. Boil $\frac{1}{2}$ hour, bottle or paste down. Very nice for apple cake, tarts or apple sauce.

Mulberry Syrup.—4 $\frac{1}{2}$ lbs. ripe mulberries, 1 bottle white vinegar. Crush mulberries with the vinegar and leave for three days. Strain. Take 1 cup sugar to 1 cup of liquid. Boil for 20 minutes. Bottle whilst hot and cork when cold.

Mason Jar Preserves.—Make a syrup of 2 cups boiling water, 1 cup sugar. Peel and cut up fruit, cook until tender, but not to a "mash." With a fine fork lift carefully into heated jars, pour syrup over until overflowing, quickly screw down, and turn the bottles upside down. If any air escapes, unscrew, fill up again quickly.

Crystallised Figs.—6 cups sugar, 3 cups water, 3 tablespoons vinegar. Bring to boil, put in 6 lbs. figs (tailed and pricked), boil from 2 $\frac{1}{2}$ to 3 hours gently, lift out and leave draining. Dry in shade. Second day roll in castor sugar.

Preserved Fruit.—To every quart of water allow $\frac{1}{2}$ lb. sugar, make a syrup. Pack fruit into jars and when the syrup is cold, pour over fruit. In the preserving pan, or copper, cover the bottom well with straw, put in bottles just lightly screwed down, and pack straw around bottles. Fill copper with water about three-quarters of the way up jars. Slowly bring to a boil, about 1 hour.

Preserving Fruit in Screw Top Honey Jars.—Procure an old motor car tube, a very thick one is best; then cut from it rounds the exact size of the inside of the lid, the piece of cardboard that is in the lids when bought with honey in, is the pattern to use to cut rubber. Pack jars with fruit and syrup, wash rubber rounds very thoroughly and put inside lids (they must fit in nicely), then screw down as tightly as possible. Do not screw lids again after taking them out of steriliser, as this will probably shift rubber, which has only a very small rim to rest on.

Some difficulty may be found in removing the lids. If bottles are stood upside down in boiling water for a few minutes, this loosens rubber and may be easily screwed off, and lids used again next year, or many years if taken care of and not allowed to rust.

Carrot Marmalade.—4 each medium sized carrots and lemons. Grate carrots finely, cut up lemon small, put them together in the preserving pan and add 4 pints of water and let stand for 24 hours. Boil for 1 $\frac{1}{2}$ hours, then add 4 lbs. sugar and boil for 1 hour more, or until set.

Loganberry Jam.—Gather berries and weigh them and boil for 30 minutes. Then add 1 lb. of sugar to each pound of berries and boil another 20 minutes.

Preserved Figs.—15 lbs. ripe figs, 9 lbs. sugar, 7 cups water, $\frac{1}{2}$ lb. whole ginger. Soak ginger all night, add to the syrup which has been made of the water and sugar, add figs and keep pressing down. Do not stir. Boil for about 4 hours. Add rind and juice of 3 or 4 lemons, or 1 teaspoon citric acid.

Apple and Blackberry Jam.—3 lbs. each blackberries and apples, 6 lbs. sugar, 4 cups water. Put apples and blackberries through mincer, add water, boil $\frac{1}{2}$ an hour, then add sugar, boil another 2 hours.

Apple and Dark Plum Jelly.—To 1 quart water allow 1lb. apples, and to each 4lbs. apples add 1lb. black plums. No water allowed for plums. Boil for $\frac{1}{2}$ hour, strain through cheese cloth bag, and allow to drip overnight. Measure liquid and boil liquid 10 minutes before adding sugar. Allow 1 cup sugar to each cup liquid. Boil about 1 hour or until it jells when tried.

Preserve Orange or Lemon Peel.—Soak peel in salted water for 3 or 4 days, drain in clean water and boil until soft. Make syrup by boiling 2 cups sugar with 1 cup water for 5 minutes. Put peel, which should be well drained, into a basin and pour syrup over it. Let stand for 5 or 6 days. Drain off syrup and boil up for 20 minutes. Put peel back in boiling syrup and boil very slowly for 20 minutes or until it looks clear, spread on a dish, sprinkle with sugar, and dry in sun or a cool oven. Lemon peel may be put through mincer and stored in jars ready for use.

Fig Chutney.—3lbs. each ripe tomatoes, onions, and brown sugar, 1lb. sultanas, 4lbs. figs, 2 tablespoons salt, 1 tablespoon ground ginger, 1oz. garlic, $\frac{1}{2}$ oz. chillies. Cut up and cover with $\frac{1}{2}$ gall. of vinegar. Stand over-night and next day boil for 2 hours.

Fig Jam.—12lbs. ripe figs which have been peeled, sprinkle 9lbs. of sugar and leave over-night. Put on stove next day and when boiling add 1 tablespoon of citric acid. Boil for 2 hours, just before removing from fire add $\frac{1}{2}$ lb. preserved ginger.

Marmalade—Grape Fruit.—To every measure of cut up fruit add 3 of water. Second day boil and measure again; then add measure of sugar to every 1 of marmalade. Boil until jells.

Gooseberry Marmalade.—3lbs. gooseberries, 3 pints water, 6lbs. sugar. Put all together in preserving pan and bring quickly to boil. Boil until red (about 1 hour).

Tomato Sauce.—14lbs. tomatoes, 2lbs. onions, 1oz. garlic, $\frac{1}{2}$ salt, 1lb. sugar, 1oz. ginger. Boil 2 to 3 hours, strain and add $\frac{1}{2}$ dram each oil of cloves and spirits of wine, 3ozs. acetic acid, 40 grains of cayenne. Return to pan and boil 1 hour.

Fig Jam.—Peel and cut up figs, then weigh fruit. Place in preserving pan and to every pound of figs allow $\frac{1}{2}$ lb. sugar. Put half the required amount of sugar on and the rest when fruit comes to the boil. Juice and rind of 1 or 2 lemons, and $\frac{1}{2}$ lb. green ginger. Boil slowly until well set when cool on saucer.

Tomato Chutney.—2lbs. peeled tomatoes, 1lb. each brown sugar, white sugar, sultanas, and dates (cut small), $\frac{1}{2}$ lb. preserved ginger, 1 teaspoon cayenne pepper, 2ozs. salt, 1oz. garlic, 3 cups vinegar:—Boil tomatoes in vinegar until soft. Add other ingredients, boil for 25 minutes.

Green Tomato Chutney.—3lbs. green tomatoes, 1 tablespoon salt, 3 pints vinegar, $\frac{1}{2}$ teaspoon cayenne, 1lb. raisins, 1 tablespoon mustard, 1 $\frac{1}{2}$ lbs. sugar, 2ozs. whole ginger, 2lbs. each cooking apples and onions. Slice tomatoes and cook until soft with half vinegar. Put through sieve and return to pan. Mince apples, raisins, and onions, all add to pan with sugar, seasoning and rest of vinegar. Tie ginger well bruised in muslin bag. Boil $\frac{1}{2}$ hour. Bottle when cold.

Pear and Tomato Jam.—Take equal quantities of pears and tomatoes, allow $\frac{1}{2}$ lb. sugar to each 1lb. fruit. Peel and cut up pears. Peel tomatoes by dipping in boiling water for a minute and then in cold, cut them in half and add to the pears. Strew half the quantity of sugar over the fruit and leave all night. Next morning add the rest of the sugar and boil until it thickens—about 2 hours, longer if a large quantity is made.

Peach and Apple Jam.—2lbs. each peaches and apples, 3 pints water, 3lbs. sugar. Peel, core, and slice apples and put in pan with water, boil $\frac{1}{2}$ hour, then add peeled and cut up peaches and boil $\frac{1}{2}$ hour; add sugar and boil 1 to 1 $\frac{1}{2}$ hours longer. When cool, bottle and seal.

Tomato Jam.—6lbs. yellow tomatoes, 2lbs. pears, 12 passion fruit, 4 $\frac{1}{2}$ lbs. sugar. Boil for 2 hours.

Apricot and Pineapple Jam.—8lbs. ripe apricots, 6lbs. sugar, 1 large tin pineapple. Put half sugar on over-night, in the morning add the remainder of the sugar and pineapple and boil 1 hour.

Sweet Pickled Gherkins.—Cover gherkins with water and salt, and stand for 8 days, then drain off liquid and dry gherkins with cloth and pack in jars. *Method:* Boil sufficient vinegar to cover gherkins; to each quart add $\frac{1}{2}$ pepper corns, 4 cloves, 2 blades of mace, a few caraway seeds, 1lb. sugar. Boil 10 minutes and pour while boiling over gherkins. Each day for about three days pour this liquid off into a saucepan, bring to the boil and pour back on the gherkins. This will make them crisp and bring back the green color.

AUBURN (Average annual rainfall, 24in.).

February 23rd.—Attendance, 14.

QUESTION BOX.—What makes gherkins turn green in pickle? *Ans.:* Boiling the vinegar several times and pouring on to the gherkins which are packed in a jar with spinach or vine leaves. Does salt improve the flavor of jam? *Ans.:* Yes; it is a great improvement to jam, about 1 teaspoon to 12lbs. of fruit. What is the best way to clean a white hat? *Ans.:* Use petrol, eucalyptus, or warm flour. To take ink stain out of silks. *Ans.:* If the stain is fresh, soak in new milk until it turns sour, or use salt and lemon. To make the Bureau meeting more interesting. *Ans.:* Let every member take an active interest in the meetings, and introduce fresh subjects for discussion. **Household Hints.**—Keep in a convenient place a basin in which a cup of oatmeal has been mixed with a teaspoon of boric acid, and rub hands with the mixture when work is completed. Another good mixture for the hands is equal parts of lemon juice, glycerine, and methylated spirits. To cure hicoughs, take slowly small sips of water; if not effective, sip a little vinegar. The easiest way to wash windows is with a piece of chamois leather because it is not necessary to dry them. Care must be taken that the washing water is clean and the cloth squeezed dry when wiping the glass. To treat chilblains. Steep the affected parts in water as hot as can be borne; when scalding becomes unbearable, plunge momentarily into cold water. Repeat the hot dip several times. This cure must not be attempted with broken chilblains. At night time apply tincture of iodine. When dealing with broken chilblains an antiseptic dressing is necessary. Very strict attention should be paid to cleanliness. Dress with boric acid ointment. Now and then dip the affected part in a weak peroxide of hydrogen bath. (Secretary, Miss. L. Dennison.)

LAURA BAY.

February 13th.—Attendance, 13.

SMALLGOODS.—The following papers were contributed by Mesdames Hoffrichter and Blumson:—"After the pig has been scalded, scraped, and washed, remove the head, cut into quarters, and wash several times, then put in a copper half full of water and boil for three hours or longer. Add the other parts of the pig when boiling the head, except the liver—the latter requires only half an hour's boiling. **Black Pudding No. 1.**—Mince part of the head, heart, and lights, some meat and fat cut into squares, half pint of blood, salt, pepper, allspice, sugar, thyme, and marjoram to taste; mix all together thoroughly, then fill in runners, which must be thoroughly cleaned; they usually take three to four hours to clean with salt and warm water. **Black Pudding No. 2.**—Same ingredients as No. 1, but add one to two cups of well boiled rice, and the meat must be all minced. Mix well and fill in runners, not too tight, to allow for swelling. Boil from quarter of an hour to an hour according to sizes. **White Pudding.**—Mince some head meat, liver, and kidneys, use same spices to taste. Take two cups of broth from the copper in place of blood. Mix all together and fill in runners. **Saveloys.**—Take half quantity of cooked and raw meat minced, say, 1 pint of each, and 1 pint of broth, 1 teaspoon salt, $\frac{1}{2}$ teaspoon of saltpetre, and $\frac{1}{2}$ teaspoon of caraway seeds. Fill in runners, scald them in a dish, then hang up for a week or longer. Before using boil them in water for 10 minutes. **Metwurst.**—6lbs. of pork, 4lbs. of beef, 2lbs. of fat, 4 tablespoons of salt, 3 tablespoons of pepper, 1 tablespoon of saltpetre, 2 tablespoons of sugar, half a wine glass of brandy, and a little garlic if liked. Fill in beef runners and smoke. Repeat for a month before using."

SOAP MAKING.—"Save all fat that is free from salt. Some favor the receipt on the caustic soda tin, which is—Dissolve 1lb. of caustic soda in 3 pints of water—the liquid will become quite hot. Then heat 6½lbs. of fat over a fire until it becomes liquid. Let it cool, and then pour into the caustic lye, slowly stirring with a spoon until it is well mixed and has the appearance of honey. Stir for 2 minutes only. Pour into a lined mould and leave in a warm place until next day, then cut up; ready for use in four weeks. For toilet soap—Glycerine (½lb.), some lux, ½lb. palm olive oil; stir until mixed. Another receipt—½lb. honey, ½lb. oatmeal, and 2 teaspoons

of lavender. Small tobacco tins are very handy in which to set toilet soap. Each of the above are added to a quarter of 6lbs. making of the usual soap recipe. Another recipe—6lbs. fat, 1lb. resin, 1lb. caustic soda, $\frac{1}{2}$ lb. borax, 14 pints of water. Lux is an improvement, and a knob of blue is recommended. (Secretary, Mrs. D. Morrison.)

McLAREN FLAT.

March 1.—Present: 20 members.

Mrs. J. Foggo gave a demonstration of tatting. The result of the Dark Fruit Cake Competition was as follows:—First prize Miss F. Bell and second prize Miss M. Ward. Mrs. J. Bruce acted as judge.

Fruit Cake Recipes (winning recipe).—1lb each butter and sugar, 1doz. eggs, 2lbs. currants, $\frac{1}{2}$ lb. mixed peel, $\frac{1}{2}$ lb. sliced blanched almonds, 1 grated nutmeg, 1 teaspoon mixed spice, 1 wineglass dark brandy, $1\frac{1}{2}$ lb. plain flour. Method: Beat butter and sugar to a smooth cream, add eggs, two at a time, beating them thoroughly through the mixture, add flour and other ingredients, sprinkle brandy over the whole, and beat lightly but well. On the thoroughness of the beating depends the lightness of this cake, and on the length of baking the color. Bake in a very slow oven $3\frac{1}{2}$ to 4 hours.

Fruit Cake without Rising (second prize).—1lb. each butter and sugar, 1doz. eggs, 2lbs. currants, 1lb. raisins, $\frac{1}{2}$ lb. mixed peel, $\frac{1}{2}$ lb. blanched almonds, 1 grated nutmeg, 1oz. mixed spice, $1\frac{1}{2}$ lbs. plain flour, essence of lemon, a little brandy. Cream butter and sugar, add well-beaten eggs, mix well, add currants, raisins, lemon peel, and almonds. Then add nutmeg, spice, and flour sifted together; lastly, add essence of lemon and brandy and mix all well together for five minutes. Put in well greased tins, cook in moderate oven for about 3 to 4 hours.

Dark Fruit Cake, without Rising, or Soda (Mrs. B. Elliott).—4 cups plain flour, 3 cups brown sugar, $1\frac{1}{2}$ lbs. currants and seeded raisins, $\frac{1}{2}$ lb. each lemon peel and almonds, 1lb. butter, $\frac{1}{2}$ lb. dripping, eggcup brandy, $\frac{1}{2}$ packet mixed spice, 3 teaspoons cinnamon, 1 grated nutmeg, 3 tablespoons cocoa, 2 teaspoons essence lemon or vanilla, 9 eggs. Bake $2\frac{1}{2}$ to 3 hours. This mixture makes three cakes. Method: Beat butter, dripping, and sugar to a cream, add eggs, which have been beaten 15 minutes, then add brandy and essence, sift in flour and mix thoroughly, add fruit and spices lastly, and mix well together. Put all fruit and almonds into a bowl, and flour well, and mix together, before putting into mixture.

Fruit Cake (Mrs. W. Cooper).— $\frac{1}{2}$ lb. each butter, sugar, sultanas, and currants, $\frac{1}{2}$ lb. mixed peel, 10ozs. plain flour, 2ozs. each shredded almonds and dates, rind and juice of lemon. Clean and prepare fruit, beat butter and sugar to cream, add beaten eggs, stir in flour, add fruit, grate rind of lemon and add juice. Mix all together.

Dark Cake (Miss R. and Mrs. B. Elliott).—Breakfast cup each butter and sugar, $2\frac{1}{2}$ cups flour, $\frac{1}{2}$ cup currants (washed and cleaned), $\frac{1}{2}$ cup pudding raisins (chopped a little), 1 cup sultanas, 4 or 5 pieces orange and lemon peel (shredded), 5 eggs, $\frac{1}{2}$ cup almonds (cut in halves), $\frac{1}{2}$ teaspoon salt, $\frac{1}{2}$ teaspoon each mixed spice and cinnamon, and juice of half a lemon. Cream butter and sugar with hand, add eggs one at a time and beat each one in well, sift the flour, salt, and spice together, add half the flour, then the fruit, then the rest of the flour, and add lemon juice last, and beat well. Put the mixture in greased tin, smooth the top, and bake in moderate oven for about 4 hours. (Secretary, Mrs. D. Elliott.)

BARLEY

We have large Overseas Representation, and are in constant touch with the World's Markets, and strongly advise Growers, before selling elsewhere, to submit samples to us for valuation.

Delivery taken at any Railway Station, Siding, or Shipping Port.

F. W. HANCOCK & CO.,

CRANBROOK CHAMBERS, BENTHAM STREET, ADELAIDE.

TELEPHONE: CENTRAL 4855 and 4856.

PARRAKIE (Average annual rainfall, 14.64in.).

February 20th.—Attendance, 12.

SAUCES AND PICKLES.—Mrs. N. Catford read the following recipes:—“*Tomato Sauce*: 15lbs. tomatoes, 1½ onions, 2ozs. garlic, 1½lbs. apples, 1½lbs. sugar, 1oz. ground ginger, 1 teaspoon cayenne pepper, 1oz. ground allspice, ½lb. salt, ½oz. cloves, 1½pints vinegar. *Method*: Break the tomatoes, peel and cut up apples, onions, and garlic, add cloves; boil all slowly together for 3 hours or more, then strain and add vinegar and other spices and boil until thick enough; strain through flour sifter. *Tomato Relish*: 12lbs. tomatoes, 4 large onions, 2 cups treacle, ½oz. cloves, ¼ teaspoon cayenne pepper, 2ozs. whole ginger (bruised), 1 bottle vinegar (1½ pints). *Method*: Peel tomatoes and onions, cut up and sprinkle with salt; stand over-night and drain off liquid; put ingredients in muslin bag and boil all together for half an hour or longer. *Tomato Chutney*: 4lbs. each tomatoes and apples, 1lb. each sultanas, brown sugar, and treacle, 1½lbs. onions, 1 teaspoon cayenne pepper, ½lb. salt, ½oz. cloves, 1½ pints vinegar. *Method*: Put all through mincer except sultanas; skin tomatoes and peel apples; boil for 1 hour.” (Secretary, Miss J. Halliday.)

PENOLA (Average annual rainfall. 26.06in.).

March 7th.—Attendance, 25.

Thirteen entries were received for the Jam Roll Competition conducted under the auspices of the Branch, the successful competitors being:—First prize, Mrs. T. Oswald; and second prize, Mrs. C. Neilson. (Secretary, Mrs. E. Kidman.)

RENDELSHAM.

February 7th.—Attendance, 12.

DRESSING POULTRY.—Mrs. W. McArthur presented the following paper:—“*Choice of Bird*—Choose a young, healthy bird, eyes bright and prominent, and legs not scaly. *To Pluck*—Scald in boiling water, drain, and then place on a piece of paper. Pluck feathers starting at legs and pulling feathers sharply towards head, then singe. Ducks and geese scalded and wrapped in a bag to steam makes plucking easier. *To Clean*—Have ready a dish of water, scissors, plate, and knife. Cut a slit in skin at back of neck, pull neck out and cut as close to the body as possible. Remove wind-pipe and crop and loosen inside. Cut a slit at the back of the bird between the vent and the tail and remove inside. Cut out vent and rinse bird under running water. Remove gall bladder from liver, cut half way through gizzard, removing centre, and wash well. Cut off legs at joints. *To Truss*—Place wings behind neck and tie legs down to tail. *To Season*—Sage and onion is used for ducks and geese and thyme and onion for fowls and turkeys, mixed with breadcrumbs and seasoned with pepper and salt, blended with an egg. *To Cook*—There are various ways of cooking and serving poultry. Steamed in a boiler until tender and then browned in the oven is especially suited for an old bird. Boiled fowl served with parsley sauce makes an excellent winter dish and the stock can be used for soup with vegetables and barley. Curried fowl is also a winter dish; joint the fowl and stew until tender with onions or other vegetables if desired. Thicken, flavor with curry, and serve with boiled rice. Fried sausages served with roast turkey are an improvement.” (Secretary, Mrs. E. Andrews.)

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Bureau Conferences.

District Conferences will be held as follows:—

River Murray, at Barmera, Friday, June 22nd, C. W. Till (Secretary).

Eyre's Peninsula (West), at Ceduna, Wednesday, July 4th, A. R. Maguire, Mudamuckla (Secretary).

Upper North, at Wilmington, Wednesday, July 18th, Chas. Cole (Secretary).

In each case the Conference will commence at 10.30 a.m. Members of Branches are invited to submit papers and questions for the agenda.

Pruning Competitions.

McLaren Flat, at McLaren Flat, June 16th.

River Murray—Mypolonga (date to be fixed); Cadell, June 26th; Waikerie, June 27th; Moorook, June 28th; Barmera, June 29th; Berri, July 3rd; Renmark, July 4th; and the championship at Berri, July 5th.

Imperial Fruit Show, 1934.

Advice has been received by the Department of Commerce that the Spring Section of the Imperial Fruit Show has been discontinued. This decision has been reached in view of the lack of interest displayed by growers of apples and pears in Australia, New Zealand, and South Africa.

Rothamsted Experimental Station—Annual Report, 1932.

The answer to the question, "Why continue agricultural research at a time when many farmers cannot sell profitably what they do produce?" is to be found in the words of Sir John Russell in his Report for 1932 of the Rothamsted Experimental Station:—"Scientific investigations in agriculture are primarily for the purpose of obtaining information, and this will always be needed so long as farming continues. It is in times of difficulty that expert information about soils, crops, and animals is most valuable to farmers, for it enables them rapidly to alter their methods in accordance with the rapidly changing economic conditions." The work described in the Report shows the type of information that is being gained in order to deal with changes in modern conditions. The price of the Report is 2s. 6d.

Tobacco Instructor.

Mr. R. E. Courthorpe-Giles, who was recently appointed Tobacco Instructor in the Department of Agriculture, has had a wide experience in the Tobacco Industry both as a grower and on the commercial side. Prior to the Great War, he was engaged in the cultivation of tobacco on a large estate at Makwiro, Southern Rhodesia, and in 1920, after receiving his discharge from war service he continued his work in the industry until 1931.

He learnt tobacco grading at the extensive tobacco grading warehouse in Salisbury, Southern Rhodesia. All growers in the country utilise the services of the Company's Sales Service, including those growers who are competent to grade and classify leaf for export to the London market and who are permitted to re-order their own leaf and that belonging to other growers in their particular locality.

In the Lalapanzie district he built and conducted a warehouse in which the tobacco grown over a large area was graded and re-ordered.

Mr. Giles was Secretary of the Lalapanzie Tobacco Growers' Association, a member of the Rhodesia Tobacco Growers' Association which was responsible for the grading of all tobacco exported from the country, and correspondent for the principal Rhodesian papers on matters of interest to the industry and to the Association.

Prepare FOR THE WET SLIPPERY ROADS

MANY times during this winter, and the power of your tyres to grip may prevent serious accident. Your wisest, safest plan is to discard worn-smooth covers and fit new Dunlops now. The deep, helical tread grips the road like one helical gear grips another—"Gold Seal" ITS FULL WIDTH.

In addition to year-round safety, Dunlop offers longer mileage and a unique SILENT RUNNING. And your local dealer quotes the lowest prices ever known!

DUNLOP

Gold Seal 

In 1932 Mr. Giles came to Australia and spent 12 months with a leading growing and manufacturing company in Western Australia. There he had charge of the tobacco stocks, grading, re-ordering and handling Australian, American, Turkish, and Macedonian leaf and acted in an advisory capacity to growers connected with the company. The latter work necessitated visits to the fields, and in this way he became acquainted with the local conditions in relation to growing and curing.

His commercial knowledge of the industry together with his experience in field work, buildings and plant, soil selection, cultivation and curing of the leaf will be of material assistance to those growers with whom he will come in contact in South Australia.

VETERINARY INQUIRIES.

[Replies supplied by Veterinary Officers, Stock and Brands Department.]

Agricultural Bureau, Cherry Gardens, asks if stock chewing bones of poisoned rabbits are likely to suffer any harm.

Reply—The skeletons of poisoned rabbits would not contain such poisons as strychnine, phosphorus, &c., although the rabbit carcasses may contain sufficient to affect stock. It is not uncommon for cattle and occasionally sheep which are suffering from mineral deficiency in their search for mineral matter to chew bones or even eat the carcasses of animals (including rabbits). Such bones and carcasses frequently contain poisons which are not minerals like strychnine, but which are manufactured by certain germs. These poisons can cause the disease known as botulism or dry bible. It is usually fatal and there is no cure. For this reason, all stock-owners should as far as possible clean up their farms of bones and make proper provision (burning or deep burial) for the disposal of all carcasses.

Frayville Agricultural Bureau asks: "Is there any difference between impaction and dry bible?"

Reply—"Impaction" is the term used to describe any case of indigestion where the bowels are overloaded with food. In the case of the cow, the rumen or big paunch which fills up most of the left side of the belly is the part of the bowel most commonly affected. "Dry Bible."—This term is a loose one, and is used by the farmer to describe several conditions, such as:—(1) Any digestive trouble of the cow. (2) The unthrifty debilitated condition which occurs in the cow during the dry period of the year. It is usually accompanied by impaction of the rumen and a depraved appetite (chewing of bones, rotting carcasses, and other rubbish) is generally present. The cause is a want of proper nourishment and a deficiency of mineral matter, mainly phosphorus. Better feeding and the provision of a phosphate lick will give a cure. (3) "Botulism."—This disease occurs as a result of No. 2. Bones and rotting carcasses of any dead animal frequently contain a poison known as a toxin, which is manufactured under certain conditions by certain bacilli which invade the carcass. Cattle which have a depraved appetite and which, in their attempt to satisfy their craving for mineral matter, chew such infected material, will get botulism. The disease is usually fatal, and treatment is not satisfactory. Usually several cattle are affected, and generally the best ones contract the disease as their mineral requirements are greater. The affected animal goes down, is unable to rise, and frequently cannot chew or swallow its food, in which case there is considerable salivation and the tongue may protrude from the mouth. The animal may make attempts to feed, but cannot swallow. The only satisfactory way of dealing with this disease is by prevention, and this consists in:—(1) The provision of good feed. (2) Making available a suitable phosphatic lick:—*e.g.*, dicalcic phosphate (35-37 per cent. P_2O_5), 40 parts; salt, 60 parts. (3) The clearing of the farm of all bones and carcasses and their disposal by burning or burying deeply in a suitable place.

Miltalie Agricultural Bureau reports horses with recurring sores below ears.

Reply—The animals are affected with a form of strangles. Those affected should be spelled from work and kept in comfortable quarters, preferably isolated away from other healthy horses. The abscess formations should be fomented with hot water, and when ripe should be carefully opened with knife or scissors, &c., so that they can be effectively drained of their purulent contents and the abscess cavity thoroughly irrigated out daily with weak antiseptic solutions, such as lysol, 1 to 2 tablespoons to 1 pint warm water, followed immediately with weak tinct. iodine (tr. iod. 1 part, water 4 parts). The skin immediately underneath the opening of the abscess should be kept smeared with vaseline to protect it from the scalding effects of the discharges. The openings of the abscesses should be kept open and not allowed to heal over until all discharges have ceased, and it may be found necessary from time to time to insert the finger to do this. These abscesses have a tendency to heal over too quickly, and then after a time they break out again. This is apparently what has happened in one case.

Mindarie reports death of horse, heavy breathing, distressed appearance, throwing head up and down, and sweating profusely.

Reply—The symptoms shown by the mare were those of acute colic, and from the *post mortem* it would appear as if the animal's death was occasioned by a rupture of the bowel. It is more than probable that the heavy infestation of blood worms, together with the sand, were responsible for inducing the attack of colic. A useful remedy for sand is a drench of 1lb. honey and 1 pint of new milk or 1½ pints raw linseed oil and 4 tablespoons of turpentine can be given. The drench should be followed by giving draughts of strong black coffee or teaspoon doses of powdered nux vomica twice a day on back of the animal's tongue. The animal's diet should, if possible, include a regular allowance of green feed and a periodical bran mash. *Re* treatment of blood worms. The animal should be starved for 24-36 hours, then given the drench of linseed oil and turpentine mentioned above. Subsequently for a fortnight give 1 tablespoon of Fowler's solution of arsenic night and morning in damped feed.

Brentwood reports death of two-year-old colt. Testicles swollen, eyes sunken in head, hind legs very stiff. Also colt with sores on hock and heel.

Reply—I cannot state cause of death. The swelling of the testicles in the early stage points to some diseased condition there, *e.g.*, a rupture, and only a careful inspection of the part would determine the abnormality present. For the colt with hock and heel sores, dress sores with the following mixture for 4-5 days:—Creosote, 1 part; oil of turpentine, 6 parts; raw linseed oil, 20 parts; then apply an ointment of sulphur and lard. Further, give 1 tablespoon of Fowler's solution of arsenic in a small damped feed night and morning for 10 days. If any green feed available give a liberal ration daily. Regulate bowels by bran mash.

"FARM MACHINERY."

The Library of the Department of Agriculture acknowledges the receipt of "Farm Machinery," by Archie A. Stone, of the American Society of Agricultural Engineers. Profusely illustrated and covering a wide range of agricultural machinery, this volume should prove a valuable source of instruction to the student as well as to the practical farmer. It graphically shows the construction of the machines and gives useful hints when repairs are necessary.

FEEDING GRAIN TO SHEEP AND LAMBS.

Appended are replies by Mr. W. J. Spafford (Deputy Director of Agriculture) to questions asked by the Clanfield Agricultural Bureau on feeding grain to sheep and lambs:—

1. *Which of the following grains have the greatest food value for the hand-feeding of sheep and lambs—Wheat, oats, and barley?*

The analyses and digestibility of the various constituents of the grains mentioned enable us to make comparison between them, and so the figures are submitted:—

COMPOSITION.

	Water.	Ash.	Crude Protein.	Fat.	Nitrogen-free Extracts.	Fibre.
	%	%	%	%	%	%
Plump wheat (63½lbs.)	10.0	1.6	8.5	1.8	75.7	2.4
Shrivelled wheat (51½lbs.) . .	10.0	1.7	9.6	1.9	73.7	3.1
Prior barley	10.0	2.8	8.3	1.3	73.4	4.2
Roseworthy Oregon barley . .	10.0	2.7	11.9	1.1	68.6	5.7
Early Burt oats	10.0	3.5	8.6	7.3	59.4	11.2
Algerian oats	10.0	3.5	9.7	5.0	58.9	12.9

DIGESTIBLE NUTRIENTS.

	Crude Protein.	Fat.	Nitrogen-free Extracts.	Fibre.	Starch Equivalent.	Nutrient Ratio.
	%	%	%	%	%	
Plump wheat (63½lbs.) . .	7.0	1.1	69.6	1.2	75.7	1 to 10.4
Shrivelled wheat (51½lbs.)	8.5	1.2	66.4	1.6	72.3	1 to 8.3
Prior barley	5.8	1.2	67.5	1.4	76.1	1 to 12.3
Roseworthy Oregon barley	8.3	1.0	63.1	1.9	72.7	1 to 8.1
Early Burt oats	6.5	5.8	45.2	3.1	62.0	1 to 9.1
Algerian oats	7.3	4.0	44.4	3.6	58.9	1 to 7.8

It is only possible to compare properly foodstuffs of similar nature, as, for instance, grains with grains, hays with hays, greenstuff with greenstuff, &c., and for the purpose it is necessary to know the Starch Equivalent and the Nutrient Ratio of each food. When the moisture-content is equal a comparison between the Starch Equivalents is a very reliable comparison between the foodstuffs as regards the fattening properties and the power to retain existing condition on the animals. The Nutrient Ratio, on the other hand, is a fair guide as to the value of the various foods for the production of milk, eggs, and growth in young animals.

The Starch Equivalent figures disclosed in the above table show that for the fattening and maintenance of sheep there is little to choose between wheat and barley, and that both of these are much better than oats for the purpose. There is also little difference in the Nutrient Ratios of the wheat and barley, so they are about as good as one another for lambs, as well as for mature sheep. Oats, with lower Starch Equivalent, and narrower Nutrient Ratio, is a little better as a Milk-producer than the other two cereals.

What the figures do show is that although shrivelled wheat has a lower fattening value than plump wheat, it has more value for the production of milk and eggs, and a similar thing applies to Roseworthy Oregon barley as against Prior barley.

2. *Would grains be better if soaked for 36 to 48 hours before feeding to sheep and lambs?*

The feeding value of grain is generally improved by soaking it, but it is not always economic to go to the trouble and expense of soaking, and great care is necessary to keep utensils clean, and to prevent the development of moulds or excessive acidity.

The value of soaking can be taken to approximate the following figures:—

5lbs. dry whole grain to produce 1lb. increase of live weight.

4½lbs. soaked grain to produce 1lb. increase of live weight.

4lbs. ground grain (dry) to produce 1lb. increase of live weight.

When soaking grain only sufficient water should be used so that it will all be absorbed by the grain, without leaving a surplus in the utensil.

3. *Which of the foregoing grains is recommended to hand-feed to lambs nearly fit for market?*

At ruling prices barley would probably give best results with forward store lambs.

4. *How much grain should be fed to ewes and lambs each day when there is plenty of roughage?*

For the first few weeks after the lambs are dropped, from 1lb. to 1½lbs. of grain per ewe per day should be ample where there is plenty of roughage, and this will gradually be increased, as the lambs grow, to 2lbs. per ewe per day.

5. *How much grain each day to lambs nearly fit for market?*

For lambs approaching marketable condition 1lb. to 1½lbs. per lamb per day will top them off quickly.

When starting to hand-feed strong sheep or lambs with grain it is essential to bring them on to full feeds very slowly. For instance, if they are to receive eventually 1½lbs. of grain per day, they should be started on 6ozs. to 8ozs. per day for three or four days, 10ozs. to 12ozs. for two or three days, 14ozs. to 16ozs. for a couple of days, and then on to full rations.

If the animals are on the weak side a longer period should be taken to get them used to the grain.

RAISING FAT LAMBS ON SUBTERRANEAN CLOVER PASTURE LANDS.

[By L. J. Cook, R.D.A., Manager Kybybolite Experimental Farm.]

During 1933, at the request of the local Branch of the Agricultural Bureau, a small experiment on the raising of export fat lambs was conducted at the Kybybolite Experimental Farm.

The idea was primarily to compare the development of various crosses when grazed on our improved subterranean clover pastures, but the scope of the work was restricted by the funds and labor available. No attempt could be made to test the various breeds or crossbreeds of ewes as mothers, but a trial of four of the more important British breeds of rams used on Comeback ewes was carried out.

Comeback ewe: Type used for breeding fat lambs.

The Farm has for some seasons been breeding a good utility line of Comeback ewes, the result of mating Merino rams back to half-bred English Leicester x Merino ewes, and it was decided to use a selected line of these as mothers for the lambs. Four flocks, containing 46 ewes in each, were carefully selected, even in type, development, age, and live weight. Each flock consisted of 17 four-tooth and 29 six and eight-tooth ewes, and the average live weight at mating time was 116.8lbs. each. They were mated to the rams on February 18th, 1933.

The four sires used were of the following breeds:—Suffolk, Dorset Horn, Southdown, and English Leicester, and we were indebted to Messrs. C. Duval, H. B. Schinckel, and the Roseworthy College for the loan of typical two-tooth rams of the three former breeds.

Whilst being mated the flocks were grazed in fields of approximate equal area, and containing similar pasturage, but after mating all the ewes were run together as one flock, and grazed under the rotational system on good fertilised clover

pastures. Early in July the flock was divided into its four sections, and each run on similar type of clover pasture during the lambing period. Lambs commenced to arrive on July 15th.

After marking, lambs and ewes were again run together as one flock. During the whole period neither ewes nor lambs were handfed, and they existed and grew entirely on grazing.

The ewes received usual attention, being crutched a few weeks before lambing, and one case of foot-rot was treated.

The flocks were examined twice daily during lambing, and note of births was taken. Three ewes were given assistance, one each in lamb to the Suffolk, Southdown, and Dorset Horn. Two ewes died at lambing, one in lamb to Suffolk, and one in lamb to English Leicester. All the other ewes maintained good health, and no further losses occurred amongst the ewes whilst the lambs were mothered.

LAMBING RESULTS.

The following table shows the number of lambs born, died, marked, and marketed from each of the four flocks:—

Ewes Mated.	Ewes Failed to Breed.	Ewes Died.	Total Lambs Born.	Lambs Born Dead.	Lambs died between Birth and Marking.	Lambs Marked.		Lambs died between Marking and Marketing.	Lambs Marketed.
						No.	%		
46 Southdown x Comeback ..	1	—	61	6	5	50	108.7	3	47
46 Dorset Horn x Comeback .	2	—	65	8	7	50	108.7	5	45
46 Suffolk x Comeback ...	3	1	55	2	2	51	113.3	7	44
46 English Leicester x Comeback ...	2	1	64	3	7	54	120.0	3	51
Total ...	8	2	245	19	21	205	112.6	18	187

It will be noticed that the Dorset Horn and English Leicester crosses were approximately equal in prolificacy, with 65 and 64 lambs born respectively, and were closely followed by the Southdown cross with 61 births, whereas the Suffolk cross produced only 55 lambs. The latter, however, were the strongest lambs, and only 4 of them were either born dead or had died before marking; whereas the losses of others were considerably greater, namely, 15 Dorset Horn cross, 11 Southdown, and 10 English Leicester cross. The majority of these deaths were amongst the twins. Only one lot of triplets was recorded, and these were born and reared in the Southdown flock.

The marking was done at three periods, August 25th, September 21st, and September 28th, and a total of 205 of the 245 lambs born were marked, being an average of 112.6 per cent. over the four flocks. The English Leicester cross was highest with 120 per cent., the Suffolk cross second with 113.3 per cent., whilst the Dorset Horn and Southdown crosses both realised 108.7 per cent.

Rather many losses (18) occurred between marking and marketing, but these were much increased by several unfortunate attacks made by stray dogs during November. Nine good lambs, including 5 Suffolk, 2 Dorset, and 2 Leicester crosses, died suddenly, apparently from attacks of entero-toxaemia; but the rest

of deaths were principally due to the dog attacks. The final column shows that 187 lambs (103 per cent.) were marketed, the Leicester cross providing the most with 51, the Southdown 47, Dorset Horn 45, and the Suffolk cross 44.

MARKETING OF LAMBS.

With reference to the marketing of the lambs, as the Farm is situated such a distance from the freezing works, it was impossible to send lambs immediately they were prime, and we were forced to send them when sufficient were approximately in prime condition to fill a railway truck. The main lot of 116 lambs were forwarded to the freezers on November 7th. Quite a fair number were ready a week or two before this date, but it was essential to hold them on the Farm until the full truck load was ready. The balance were kept for a later consignment, but on account of the unfortunate attacks on these by dogs they had to be held much longer than anticipated.

They were weaned, and topped on a pea stubble during January, and consigned to market on February 1st, 1934.

Southdown x Comeback lambs.

WEIGHT OF LAMBS.

As a matter of interest, and for demonstration purposes, one lamb of each cross was sent to Naracoorte on October 3rd, dressed 4 hours after being removed from the ewes, and the carcasses exhibited at the local show. The weights of these lambs, when taken from the ewes, and their dressed carcasses, when cold, were as follows:—

	Live Weight.	Dressed Weight.	Percentage.
	lbs.	lbs.	
Southdown x Comeback.. . . .	60½	32	53
Dorset Horn x Comeback	63	33	52
Suffolk x Comeback.. . . .	73	37	51
English Leicester x Comeback	58	30	52
Average	63.6	33	52

It is of interest to note that these young spring lambs, approximately 11 weeks of age, when killed only 4 hours after removal from the field, dressed 52 per cent. of their live weight. The Southdown cross with 53 per cent. dressed the best of the four, whilst the Suffolk cross with 51 per cent. was a little less than the Dorset

and Leicester crosses. However, the weights show the Suffolk cross to have been easily the heaviest lamb and quickest grower, followed by the Dorset Horn, Southdown, and English Leicester crosses in that order.

A fortnight later a further four representative lambs were sent to Mount Gambier and treated similarly, with the exceptions that the lambs were approximately 13 weeks old, had to travel considerably further, and were not killed until they had been 28 hours off their mothers. The weights of these four were as follows:—

	Live Weight.	Dressed Weight.	Percentage.
	lbs.	lbs.	
Southdown x Comeback.. . . .	62	30	48
Dorset Horn x Comeback	64	30	47
Suffolk x Comeback.. . . .	74	37	50
English Leicester x Comeback.. . .	60	31	51
	—	—	—
Average	65	32	49

From these weights it is noticeable that the lambs dressed only 49 per cent. of their live weight, due undoubtedly to the longer period of transport from field to

Dorset Horn x Comeback lambs.

slaughter. It is also apparent that both the Southdown and Dorset Horn cross lambs in this case were not quite as prime as the average of these crosses, because in all other results these have been better in comparison with the other crosses.

On the 7th November, when the bulk of the lambs would have averaged 14 weeks in age, the first consignment was sent to the nearest freezing works, a distance of 150 miles. The number and average weights of these lambs were as follows:—

	Average Live Weight.	Average Dressed Weight.	Percentage.	Weight Green Skins.
	lbs.	lbs.		lbs.
28 Southdown x Comeback ..	72.8	31.7	43.5	9.2
29 Dorset Horn x Comeback ..	75.3	30.76	40.9	8.6
33 Suffolk x Comeback .. .	75.1	30.7	40.9	7.7
26 English Leicester x Comeback	70.5	28.46	40.4	8.8
	—	—	—	—
116 Average	73.5	30.45	41.4	

On the 1st February, 1934, the second and final consignment was sent to the freezers, with the following numbers and weights:—

	Average Live Weight.	Average Dressed Weight.	Percentage.	Weight Green Skins.
	lbs.	lbs.		lbs.
17 Southdown x Comeback ..	75.3	32.19	42.7	10.1
13 Dorset Horn x Comeback..	90.2	37.08	41.1	11.07
9 Suffolk x Comeback	81.9	33.25	40.6	10.0
22 English Leicester x Comeback	83.5	32.95	39.5	11.4
61 Average	82.4	33.69	40.9	

These two tables show a greater loss of weight, due to the longer transportation, Approximately there were 7lbs. per head wastage on the 150 miles of transit. It is of special note that the Southdown cross lambs dressed appreciably better than the others in both cases. The lambs were all sold in the wool.

QUALITY OF LAMBS.

Regarding the quality of the lambs for export, the following table shows the number and percentages of carcasses of each cross, in each consignment, placed in grades by the purchasers (Messrs. Borthwicks Ltd.):—

	First Quality.	Second Quality.	Third Quality.	Rejects.
	No.	No.	No.	No.
Southdown x Comeback, 1st lot	28 } 93.3%	— } 4.5%	—	— } 2.2%
2nd lot	14	2	—	1
Dorset Horn x Comeback, 1st lot	18 } 66.7%	11 } 33.3%	—	—
2nd lot ..	10	3	—	—
Suffolk x Comeback, 1st lot	18 } 50%	13 } 40.5%	2 } 7.1%	— } 2.4%
2nd lot	3	4	1	1
English Leicester x Comeback, 1st lot	12 } 62.5%	10 } 29.1%	2 } 4.2%	2 } 4.2%
2nd lot	18	4	—	—
All breeds (totals), 1st lot	76 } 68.4%	34 } 26.5%	4 } 2.8%	2 } 2.3%
2nd lot	45	13	1	2

This table shows that of the 177 lambs sent to the freezers, 121 were classed as first quality, 47 as second quality, 5 as third quality, and only 4 were rejected. This result is quite satisfactory when it is remembered that every lamb reared in the flocks was sent to the freezers; none were held back on the Farm.

The outstanding fact is the excellent quality of lambs produced by the Southdown cross. In the first consignment this cross was 100 per cent. first quality. and the second consignment shows plainly that, although they were kept a comparatively long time on the Farm, they maintained their primeness extremely well. Only two lambs, a pair of twins that were dropped very late, and were under-sized, were put back to second quality. One lamb with a diseased joint was rejected. These Southdown cross lambs produced very fine shapely carcasses of prime quality, and comparatively even in weight.

For shape and conformation, the English Leicester cross lambs ranked next to the Southdown, but they were slower in maturing, and did not thrive quite as well as the other crosses; 50 per cent. of the first consignment of these lacked quality, mainly through immaturity, but the second consignment showed to advantage, in that 18 out of 22 lambs passed as first quality.

The Dorset Horn cross lambs were a fine lot, growing quickly, but they were lacking in conformation, and many were placed as second quality on that account; that

THE PRINCIPAL,
Agricultural College,
ROSEWORTHY.

is. the pins of the shoulders were not well covered, and there was a falling away at the hindquarters. These lambs, however, were all either first or second quality.

The Suffolk cross lambs show out to least advantage as regards quality. They were very strong, quick-growing lambs, but did not maintain their primeness well. Situated closer to the freezing works, so that the lambs could have been marketed as soon as ready, the percentage of first quality lambs amongst these would probably have been much higher. The carcasses lack in conformation more than the Dorset Horn cross.

VALUE OF THE LAMBS.

The prices paid in November at the freezers were:—

4½d. per lb. for first quality.

4d. per lb. for second quality.

3½d. per lb. for third quality.

As we were unfortunately unable to obtain separate skin valuations, we have had to base the values on an overall price, including value of skins, as follows:—

6½d. per lb. for first quality.

5½d. per lb. for second quality.

5¼d. per lb. for third quality.

The value of the first consignment was therefore as follows:—

No.	Breed.	Lamb. Lbs. Price		Total Value.	Value Per Lamb.	Less Charges 1s. 10½d. Each.
		d.	£ s. d.	£ s. d.	s. d.	s. d.
28	Southdown x Comeback ...	888 @ 6½	—	24 1 0	17 2	15 3½
18	Dorset Horn x Comeback ..	568 @ 6½	15 7 8	23 1 11½	15 11½	14 1½
11	Dorset Horn x Comeback ..	322 @ 5½	7 14 3½			
18	Suffolk x Comeback	559 @ 6½	15 2 9½			
13	Suffolk x Comeback	404 @ 5½	9 13 7	25 18 8½	15 8½	13 10½
2	Suffolk x Comeback	51 @ 5½	1 2 3½			
12	English Leicester x Come- back	364 @ 6½	9 17 2			
10	English Leicester x Come- back	273 @ 5½	6 10 9½			
2	English Leicester x Come- back	51 @ 5½	1 2 3½	18 4 10½	14 0½	12 2½
2	English Leicester x Come- back (rejects)	50 @ 3½	0 14 7			
116	All breeds	—	--	91 6 6½	15 9	13 10½

The prices in the final column show the net price per head for each cross received at Kybybolite after paying freight and commission on sale. The value of the Southdown cross, 15s. 3½d. each, was 1s. 2½d. greater than that of the Dorset Horn cross. The latter were worth 3d. each more than the Suffolk cross, whereas the value of the English Leicester cross was 1s. 8d. each less than the Suffolk, and 3s. 1½d. less than the Southdown.

The prices paid in February at the freezers were:—

5½d. per lb. for first quality.

4½d. per lb. for second quality.

4¼d. per lb. for third quality.

2½d. per lb. for rejects.

Lambskins of 6.16lbs. average dry weight were sold at 5s. 6d. each.

Suffolk x Comeback lamb.

The value of the second consignment was as follows:—

No.	Breed.	Lamb. Lbs. Price.	Value.	Value per Lamb.	Skin Value.	Gross Value.	Less Charges. 1s. 11½d.
		<i>d.</i>	<i>£ s. d.</i>	<i>s. d.</i>	<i>s. d.</i>	<i>s. d.</i>	<i>s. d.</i>
14	Southdown x Come- back	456 @ 5½	9 19 6				
2	Southdown x Come- back	59 @ 4½	1 2 1½				
1	Southdown x Come- back (reject)	21 @ 2½	0 4 4½				
			11 6 0	13 3½	5 4½	18 7½	16 8
10	Dorset Horn x Come- back	367 @ 5½	8 0 6½				
3	Dorset Horn x Come- back	115 @ 4½	2 3 1½				
			10 3 8½	15 8	5 7	21 3	19 3½
3	Suffolk x Comeback	107 @ 5½	2 6 9½				
4	Suffolk x Comeback	132 @ 4½	2 9 6				
1	Suffolk x Comeback	27 @ 4½	0 9 6½				
1	Suffolk x Comeback (reject)	27 @ 2½	0 5 7½				
			5 11 6	12 4½	5 4	17 8½	15 8½
18	English Leicester x Comeback	617 @ 5½	13 9 11½				
4	English Leicester x Comeback	108 @ 4½	2 0 6				
			15 10 5½	14 1½	5 7½	19 8½	17 9
61	All breeds		42 11 7½	13 11½	5 6	19 5½	17 5½

These returns show the Dorset Horn cross at 19s. 3½d. each net at Kybybolite to be the most valuable of the consignment. They were much heavier lambs, as shown in a previous table, and realised 1s. 6½d. more than the English Leicester cross, which were in turn 1s. 1d. greater value than the Southdown cross, and 2s. better than the Suffolk cross.

By combining the two consignments, the average prices for the season are as follows:—

	s. d.	£ s. d.	
Southdown x Comeback—			
1st Consignment 28 lambs @ 15 3½			
2nd Consignment 17 lambs @ 16 8		35 12 1	or 15s. 10d. per head.
Dorset Horn x Comeback			
1st Consignment 29 lambs @ 14 1½			
2nd Consignment 13 lambs @ 19 3½		32 19 6½	or 15s. 8½d. per head.
Suffolk x Comeback—			
1st Consignment 33 lambs @ 13 10½			
2nd Consignment 9 lambs @ 15 8½		29 18 9	or 14s. 3d. per head.
English Leicester x Comeback—			
1st Consignment 26 lambs @ 12 2½			
2nd Consignment 22 lambs @ 17 9		35 7 4½	or 14s. 8½ per head.
Total177		£133 17 9	15s. 1½d.

These figures show that the whole 177 lambs sent to the freezers realised an average price of 15s. 1½d. each at Kybybolite. The Southdown cross were the most valuable at 15s. 10d. each, and were also the most even line of lambs. The Dorset Horn cross averaged only 1½d. per head less, due to the high weight of lambs of this cross in the second consignment.

English Leicester x Comeback lambs.

VALUE OF THE FLOCKS.

Allowing average prices for the other 10 lambs that were utilised for demonstration purposes, the total return in value of lambs from each flock of 46 ewes has been as follows:—

47 Southdown x Comeback lambs at 15s. 10d.	£37 4 2
45 Dorset Horn x Comeback lambs at 15s. 8½d.	£35 6 10
44 Suffolk x Comeback lambs at 14s. 3d.	£31 7 0
51 English Leicester x Comeback lambs at 14s. 8½d.	£37 11 2

These figures show the greatest return of £37 11s. 2d. from the flock mated with the English Leicester ram, due to the extra lambs produced. The flock mated to the Southdown ram, with 4 lambs less marketed, produced only 7s. less in value.

However, as the English Leicester cross lambs were slower in maturing, some correction is perhaps necessary to allow for the extra time that lambs were pastured on the farm.

The following table shows deductions from the returns from each cross, allowing grazing of lambs at 2d. per week per head:—

	£	s.	d.	£	s.	d.	£	s.	d.
Southdown x Comeback returned	—	—	—	37	4	2			
Less 30 lambs for 12 weeks @ 2s. each	3	0	0	—	—	—			
Less 17 lambs for 24 weeks @ 4s. each	3	8	0	6	8	0			
							30	16	2
Dorset Horn x Comeback returned	—	—	—	35	6	10			
Less 32 lambs for 12 weeks @ 2s. each	3	4	0	—	—	—			
Less 13 lambs for 24 weeks @ 4s. each	2	12	0	5	16	0			
							29	10	10
Suffolk x Comeback returned	—	—	—	31	7	0			
Less 35 lambs for 12 weeks @ 2s. each	3	10	0	—	—	—			
Less 9 lambs for 24 weeks @ 4s. each	1	16	0	5	6	0			
							26	1	0
English Leicester x Comeback returned	—	—	—	37	11	2			
Less 29 lambs for 12 weeks @ 2s. each	2	18	0	—	—	—			
Less 22 lambs for 24 weeks @ 4s. each	4	8	0	7	6	0			
							30	5	2

With these allowances made, we find that the ewes mated to the Southdown ram have produced the greatest return, with £30 16s. 2d.; 11s. more than those mated to English Leicester ram, 25s. 4d. more than those mated to Dorset Horn ram, and 95s. more than those mated to Suffolk ram.

In conclusion, the experiment shows that the raising of fat lambs on the improved pastures during this season has been quite satisfactory. The return of wool from the Comeback ewes, used as mothers, was approximately 14s. per head, which, added to the 15s. 4½d. return of lamb per ewe, makes a total of close upon 30s. per ewe in gross return.

Finally, in handling fat lamb flocks on these lands, it is imperative to graze them on well-fertilised pastures. Drop the lambs sufficiently early to enable them to be marketed before the grass seeds become troublesome; otherwise late lambs should be grazed on mown areas, or, preferably, pea or oat stubbles.

It is proposed to continue the experiment over a number of seasons, with the inclusion of a flock mated to a Ryeland ram. Returns averaged over a number of seasons will provide more definite results.

THE BAKING QUALITY OF AUSTRALIAN WHEAT— DEVELOPMENTAL ASPECTS.

[ALLAN R. CALLAGHAN, D.Phil., B.Sc. (Oxon.), B.Sc.Agr. (Syd.), Principal
Roseworthy Agricultural College.]

Although the objectives of economic plant breeding are diverse and numerous if considered one by one, they all radiate to one main central objective and that is to increase the monetary returns of the grower, and for the most part this great objective remains constant.

There is a subtle yet important distinction between the policy which calls for more bushels per acre and that calling for greater returns per acre, and although it may be argued that all other considerations should be rendered subservient to yield, there is a limit to the unreserved way in which such a policy should be advocated. Even from the general viewpoint of bulk wheat exported from Australia there has been reason to call a halt to the straightout policy of increased yield to the complete neglect of quality, and while it is absurd to become panic-stricken with regard to the quality of our Australian wheat, there is undoubtedly need for a careful review of the whither and how of our future development.

There are three main avenues of wheat marketing open to Australian producers and all three must enter into any discussion on future relationships of quality standards and wheat marketed. Firstly, there is the wheat used for home consumption; secondly, the wheat that is milled in Australia and sold as flour; and thirdly, the rest of the wheat which is parcelled together and sold on the world's market according to State f.a.q.'s. For clarity these are considered separately.

WHEAT FOR HOME HUMAN CONSUMPTION.

Considering Australia at large, the wheat absorbed for home human consumption was 31,000,000bush. annually for the period 1927-32. For the same period 161,000,000bush. was the average total annual production, so that approximately 20 per cent. of the total crop was utilised for home human consumption. From this it is apparent that the wheat so used has an important relationship to the total production. During the last few years there has been an almost universal and insistent demand from the millers for better quality, and while some have encouraged the propagation of better quality wheats by offering premium prices, it must be admitted that the supply has not been forthcoming. This is chiefly accounted for by the lack of capacity for yield in existing varieties of good quality. The slogan of yield per acre has seen to this, and millers, by premium payment, have been unable to make up the margin of loss accruing as a result of the disparity in yield between the "strong" varieties and the high yielding weak-flour varieties.

From personal contact with most of the millers of this State, I am perfectly satisfied that they are very sincere in their desire to obtain varieties of higher baking quality. It is evident, therefore, that there is a happy future for a variety, or varieties, of wheat possessing good quality, provided they have yielding ability sufficient at least to compete with high yielding varieties of poorer quality. On acceptance of these varieties by the farmers, there will be no need to direct such wheat into the channels of local milling, for the demand is already there, and the millers generally see to it that they get the best wheat available. Should it happen that a home consumption price for wheat be fixed, this demand, on the part of the millers, may be exaggerated. Having to pay more for their wheat will mean that they will make greater efforts to obtain the best quality that is available. Thus, from the viewpoint of local consumption alone, there is definitely room for increased quality, and there is little doubt that a variety combining good quality with average to good yielding capacity would find ready acceptance.

THE EXPORT TRADE IN FLOUR.

The second aspect is that of flour milled for export. A very noticeable rise in the amount exported has taken place in recent years, as shown by the following figures. For the decade 1916-25 the annual average export of flour, in bushel equivalents, was approximately 18,000,000bush. For the five years representing the period 1926-31, however, the average annual export of wheat, as flour, had increased to almost 25,000,000bush. Moreover, the flour exported appears to be in answer to a very steady demand, as no serious decline in the amount exported takes place from year to year, the chief fluctuations being in the nature of steady increase. Through these channels it seems there would always be a ready market for strong wheats. There is every possibility of this method of marketing our wheat increasing, especially if trade with the East can be judiciously and wisely exploited. If this market is to be gained and held then the millers must be in a position to supply flour of the quality desired. In fact, the standardisation of the gluten content of Australian flour shipped to the East at a level sufficiently high to compete with flours of high gluten content from the U.S.A. and Canada seems to be the most pressing need of the moment. Millers have been exhorted to do this, and the only way open to them is to choose higher quality wheats. Flour of indifferent, and especially varying, quality is of no use on the Eastern markets, and while the demand for Australian wheat and flour is there, every endeavour should be made to meet it.

From this it should not be concluded that the market in the East demands only flour of high baking quality. There is a big market there, as elsewhere, for weaker flour types. It is true, however, that standardisation of gluten content is fundamental, whatever the baking quality of the flour, and this calls for systematic handling of all flour sold, according to a definite brand, the brand being the assurance in itself of a definite and standard gluten content.

Other flour markets stipulate in no uncertain manner the necessity for good baking quality, the notable case being that of Egypt, where protective legislation was passed to assure at least 12 per cent. gluten content of all flour imported, and although this legislation has been lifted, it should be taken as unmistakable evidence of their requirements.

The marketing of our wheat overseas as flour, therefore, offers a way for the marketing of better quality wheat. When better quality wheats can be offered in large quantities to our millers there is every reason to believe that they will endeavour to exploit more lucrative markets abroad. Should the market expand, consistency of flour quality, as well as continuity of supply, will depend upon increased production of better quality wheat. It is clear that this aspect offers further incentive for the planning of wheat-breeding programmes on a quality basis.

AUSTRALIAN F.A.Q. WHEAT.

Having indicated the need and advisability of developing better quality wheats from the aspects of the local market and the overseas marketing of flour milled in Australia, there remains for consideration the largest portion of our wheat crop, which is disposed of on the world's markets as Australian f.a.q. A quality survey of this wheat must be confined to the consideration of huge bulks of wheat which are handled, shipped, and sold according to f.a.q. standards set down by each State every season. Unfortunately the Australian wheat industry has grown up without casting aside these strappings of its infancy. The system of marketing on a "fair average quality" basis, which was developed and was highly suitable when our exportable surplus was very limited and small, has outgrown its usefulness now that we have taken our place among the four greatest exporting countries of wheat in the world. If a purely impartial attitude on the part of all concerned with our wheat industry could be obtained, there is little doubt that a better

system of marketing our wheats on overseas markets would eventually be adopted. Interests, however, are not impartial, and there is a very strong opposition to any departure from the f.a.q. system.

The opposing faction to marketing reform is better organised and has greater backing, unity, and driving force than those who know and feel that some reform at least would directly benefit the primary producer. This alone makes marketing reform rather a remote possibility. Further, as handling reform is an imperative precursor of grade marketing, the chances of an all-Australian policy of grading on a quality basis being realised has been further delayed as a result of the present parlous position of the industry as a whole. For some considerable time yet, therefore, good, medium, and poor quality Australian wheats will continue to be dumped together and sold as f.a.q. One naturally looks to an alternative line of approach to the problem of raising, or at least maintaining, the quality of Australian wheat sold in this manner. This responsibility is wholly in the hands of the wheat-breeders of the Commonwealth, and, if through the development of high yielding, weak flour wheats, the price of Australian wheat on overseas markets declines, then the plant-breeder may have to admit failure in attaining the objective of increasing the monetary returns of the grower. Fortunately, those responsible for the wheat-breeding in the Commonwealth are alive to this fact, but there still remain the tendency, overwhelming desire and danger, of breeders releasing for general cultivation very high yielding wheats of definitely inferior quality. If all the official wheat-breeders of the Commonwealth were to agree that no variety of wheat of definitely weak-flour strength should be released for general culture in wheat-belt areas, even though it may promise to be superior in yield to existing varieties, then the present tendency of regression in the general quality of Australian wheat would be allayed and the position eventually improved.

It is fully recognised that in certain areas, and in Tasmania in particular, only weak-flour wheats are likely to be of value. These areas, however, are limited, requiring varieties usually later maturing and very different from those which thrive in the true wheat lands of the Commonwealth. It is quite permissible, and, indeed, laudable for these areas to concentrate on high yielding, weak-flour wheats, for there is a specific market for such in the biscuit and pastry flour trade. Breeders could still concentrate on weak-flour wheats for these areas without jeopardising the quality of wheat from the main areas, for varieties bred for such special climates would never succeed competitively under the shorter-seasoned, hotter and drier regions of the wheat belt proper.

A policy, prohibiting the release of varieties other than those possessing a recognised standard of quality, not necessarily high, but definitely above the lower limits as defined by the most outstanding weak-flour varieties at present in cultivation, namely, Nabawa, Free Gallipoli, Waratah, and Early Gluyas, would undoubtedly have a beneficial effect upon the general quality of our wheat in the future. To me this is of national importance, and State jealousies, precedence, and other ambiguous hindrances should be made subservient to the need of the moment, and if an agreement could be arrived at and put into immediate operation, certainly no harm could accrue and it would safeguard the baking standard of Australian f.a.q. for the future, and, incidentally, pave the way for a more advanced system of marketing.

In an article published in this *Journal* last year I expressed the intentions of putting such a policy into operation at Roseworthy Agricultural College, where the major portion of the wheat-breeding work of the State is being carried out. At the present time the economic position overshadows all other considerations in the wheat world, but when supply and demand again take control of the market, a more exact picture of World requirements on a quality basis will be portrayed.

Whether the demand for better baking quality wheats increases or not it would definitely be to the advantage of Australia to be in a position of being able to produce large quantities of wheat of better quality at short notice to meet possible changes in demands.

In summarising the position, therefore, it must be admitted that the quality of our wheat must be studied in the future, and it would be short-sighted and damaging to frame any wheat-breeding programme without incorporating selection on a quality basis. There is evidence to show that varieties possessing strong flour characteristics would find a ready market with local millers, and that the grower would, in this way, receive the credit for this higher grade wheat. From the standpoint of our f.a.q. wheat all efforts on raising the quality of it would mean a readier sale overseas, which would probably be accompanied by better prices.

WHEAT BREEDING IN RELATION TO BAKING QUALITY.

The work of breeding wheats is, without doubt, complicated immediately the quality factor is introduced, and as quality in wheat is a very elusive character, the chief difficulty encountered by the breeder is to assess the comparative "quality" values of his selections. There is no known method whereby the exact quality of small quantities of wheat may be measured with accuracy and absolute certainty, and, until comparatively recent times, there was no method available which was even helpful to the plant-breeder in the early and most important stages of his work. The fact of the matter is that quality so far has evaded scientific definition, and while it is known that both chemical and physical phenomenon are involved, their exact nature is not clear. The final and crucial test is a baking test, and for this reason the definition of strength remains linked inseparably with

the practical capacity of a certain flour to produce large, well-shaped loaves of bread, of good colour and texture. It is known, however, that while quantity of gluten is fundamental the quality of the gluten is also of distinct importance. Thus, quantity and quality of gluten, if measurable, should give evidence of actual quality of baking ability. The wheat-breeder has been seriously handicapped for the want of some measure of quality of small samples, and in 1930 a German worker published a paper outlining a whole-meal fermentation test designed to guide the work of the plant-breeder in sorting out wheat selections on a quality basis. This test is commonly referred to as the Pelschenke Test, and it endeavours to measure the quality and the quantity of the gluten, then to combine the two factors in such a way as to express the comparative baking qualities of wheat samples under review. The test is by no means infallible, and is definitely limited in value, but to the wheat-breeder it is without question a very useful guide, which should narrow the range of selection sufficiently to enable elimination of hundreds of selections as useless from the quality viewpoint in the early stages of the work, thus avoiding congestion and confusion of innumerable fixed lines awaiting selection on baking results.

It will be argued that environment is a very potent influence on the baking quality of wheat, but it is also certain that the hereditary constitution of a given variety defines its baking quality, even though it may vary from season to season, or climate to climate. The environment chiefly affects quantity of gluten, and in countries such as Australia, where the ripening period from flowering to full maturation of the grain is short and sharply defined by warm, dry conditions, the percentage of nitrogen, which is closely correlated with the quantity of gluten, is higher than would be the case were similar varieties grown in an environment such as England, where the ripening period is prolonged, moist, and cool. The character of the endosperm is very largely affected by finishing conditions, and the longer and better the conditions the greater the percentage of starch translocated to the grain; and, correspondingly, the lower the percentage of protein which, in this case, may be termed gluten. The quality of the gluten is more dependent upon the hereditary constitution of the variety than is the quantity, and it is this factor which chiefly concerns the wheat-breeder. It is maintained, and not without good reasons, that the whole-meal fermentation test now available will act as a very useful guide for the breeder in this regard, for it will enable him to test, in a comparative way, small samples of all his selections in the initial stages of his breeding work.

The breeding of wheats at Roseworthy College, in future, embodies breeding with the object of not allowing the good name of South Australia's wheat to be lost on the score of diminished quality. The objects are to breed higher quality wheats if possible, and in all cases to breed wheats which will be acceptable in quality as in other characters when treated as f.a.q. In this way, no further retrogression may be expected, and the requirements of the local and export flour trade should be filled. The importance, therefore, of knowing as much as possible about the test being used is evident, and, for this reason, work on the subject has been undertaken at the College. If, through this work, the test can be developed and used for more extensive work than as a guide to selections in the plant-breeder's plots, and the actual limits of its reliability can be defined accurately, some very useful service will be done. With this in mind, this article, and those to follow by officers of the College Staff, have been written.

Finally, it is wise at this juncture to emphasise the fact that no claims are made with regard to the test other than it is likely to be a very useful and acceptable guide to all the wheat-breeding work being conducted at the College in the future.

PARAFIELD EGG LAYING COMPETITION, 1933-34.

A GENERAL REVIEW OF THE COMPETITION.

[By C. F. ANDERSON, Government Poultry Expert.]

The Competition was conducted at Parafield Poultry Station, and was all Single Testing. The test commenced on April 1st, 1933, and terminated on March 31st, 1934.

The principal feature of the Competition was the complete revision of the system of weighing. The previous practice of weighing the eggs was to weigh all eggs laid during the month of July, and if 60 per cent. of the eggs weighed were 2ozs. in weight or over the bird was eligible to continue in the test.

Winning Bird, Section 3, Black Orpington. Highest score in all breeds. Total, 214 first grade eggs, also highest weight of eggs for year of all birds competing. Total weight: 28.8lbs. Owned by Mr. N. F. Richardson, Woodville Park.

This method of weighing had several disadvantages, the principal objection being that a bird might have laid heavily from the commencement of the test, and by the time of the weighing might be going off in production, the size of the egg also declining. Frequently such birds, although probably some of the best birds, would fail to qualify as to the weight of eggs.

Another possibility was that a bird might lay only 3 eggs during the month of July, and if 2 of these eggs were 2ozs. in weight or over, she would be eligible to continue in the test; while a bird might lay 20 eggs or more during the same period, and just fail by 1 or 2 eggs to draw the weight. From a breeding point of view the results were not very satisfactory, as the breeder did not know the number of first-grade eggs the competing birds actually laid.

Like the majority of our other primary industries to-day, the future of the poultry industry is obscure, but if the position of quotas, &c., with regard to our surplus production does come to fruition, it is certain that the first eggs to come under the ban will be the smaller eggs, probably from 1½ozs. downwards. It is therefore essential that every attention be given to the selection of breeding stock, so that the progeny will produce a large number of standard size eggs.

With this object in view, the rules with regard to the weighing of eggs were drastically revised, and it was decided that every egg laid throughout the whole test would be individually and accurately weighed.

Winning Bird, Section 1, White Leghorn, with a total of 184 first grade eggs. Owned by Mr. F. F. Welford, 1, Ludgate Circus, Colonel Light Gardens.

For the purpose of weighing, a special set of scales was built, the accuracy of which could not be disputed. The eggs were weighed immediately after collection, which was usually between 4 and 4.30 p.m.

The following were the conditions of weighing for first grade eggs. All results of the Competition were decided in all sections on the greatest number of first grade eggs laid:—

From 1st April to 31st May a first grade egg was 1½ozs. in weight or over.

From 1st June to 30th June a first grade egg was 1½ozs. in weight or over.

From 1st July to 31st March a first grade egg was 2ozs. in weight or over.

These conditions were very different from the previous system of weighing, and competitors were therefore a little doubtful as to the class of bird to select.

On a general scrutiny of the birds when penned it was very obvious that the majority of competitors had selected birds well forward in laying so as to get as many first grade eggs as possible during the early period of the test, with the

result that a big percentage of the birds went into a moult from the middle of May, and did not come back to satisfactory production until towards the end of July. This fact clearly showed that the majority of the birds were too forward

Black Minorca. Winning Bird, Section 2 Any Other Light Breed, with a score of 156 first grade eggs. Owned by Mr. V. F. Gameau, Findon Road, Woodville.

Rhode Island Red. Winning Bird, Section 4. Score 170 first grade eggs. Owned by Mr. H. J. Mills, Edward Street, Edwardstown.

at the commencement of the test, with the result that the moult was a prolonged one. This position, of course, seriously affected the scores, and the general averages were low.

The season was not generally a good one for high production, especially during the latter two months of the test, when record hot weather was experienced, which also seriously affected the scores. Parafield temperatures are from 2 to 3 degrees higher than those registered in Adelaide.

It should be remembered, however, that with the revision in the method of weighing, which necessitated the selection and breeding of a better class of bird, that high scores could not be expected in the first year of the test. As the tests progress, and the breeders learn the type of bird to breed, the averages will undoubtedly improve.

The final results are a little disappointing to the majority of competitors, but when all conditions are carefully considered, it will be realised that a definite start has been made to raise the standard of the flocks of the State, an effort the necessity for which cannot be over-stressed.

The Competition was divided into 4 sections:—No. 1, White Leghorns; No. 2, Any Other Light Breed; No. 3, Black Orpingtons; No. 4, Any Other Heavy Breed.

The following birds competed:—

No. 1 Section—138 White Leghorns.

No. 2 Section—6 Black Minorcas.

No. 3 Section—75 Black Orpingtons.

No. 4 Section—15 Rhode Island Reds; 3 Barnevelders; 2 Welsumers.

Owing to the method of weighing of eggs, no birds were disqualified for short weight of eggs, only the actual number of first grade eggs being credited to the bird.

Deaths.—During the currency of the Competition 17 birds died, equal to 7 per cent. of the competing birds. The deaths of the breeds were as follows:—

White Leghorns, 3.

Black Orpingtons, 12.

Rhode Island Red, 1.

Barnevelder, 1.

Considering the extreme heat experienced during the last two months of the Competition, the death rate was not high.

The usual Winter Test was conducted, and the leading scores for that period (from 1st April, 1933, to 31st July, 1933) were:—

FEEDING.

The method of feeding was similar to that adopted in the previous year, and one that could be readily practised by egg producers.

Morning.—Wet mash, composed of equal parts by weight of bran, pollard, and wholemeal 1lb. meatmeal per 100 birds, and chaffed greenfeed, 40% to 60%, according to the period of the year.

The principal greenfodders used were :—Summer—Lucerne and maize. Winter—Mustard and barley.

Mid-day: Wheat.

Night: Wheat.

The quantities fed per day per bird were:—

Bran, $\frac{1}{2}$ oz.; pollard, $\frac{1}{2}$ oz.; wholemeal, $\frac{1}{2}$ oz.; wheat, 2ozs.

The following table shows the average monthly price of the various foodstuffs delivered at Parafield:—

TABLE III.—Average Monthly Price of Foodstuffs.

Month.	Wheat, per bush.	Bran, per ton.	Pollard, per ton.	Wholemeal, per 60lbs.	Meatmeal, per ton.	Onions, per cwt.
1933.	<i>s. d.</i>	<i>£ s. d.</i>	<i>£ s. d.</i>	<i>s. d.</i>	<i>£</i>	<i>s. d.</i>

	Aver. price. 35 33d.	Aver. price. £4 19 2	Aver. price. £5 0 0	Aver. price. 41 58d.	Aver. price. £12	Aver. price. 3s. 7 $\frac{1}{2}$ d.
		= 11 9d. per bushel.	= 1s. per bushel.	or 13 86d. per bushel. of 20lbs.		

The average cost of feeding per bird was 4s. 6d.

The average monthly prices received for eggs were:—

TABLE IV.—Average Monthly Prices for Eggs.

Month.	1½ozs. and Over.	1½ozs.
1933.	per dozen.	per doz.
	<i>s. d.</i>	<i>s. d.</i>
April	1 5	1 2-83
May	1 4	1 3-25
June	1 1½	1 3
July	0 11½	0 8-83
August	0 11	0 8½
September	0 11	0 8½
October	0 11	0 8½
November	0 10	0 7½
December	0 9	0 7
1934.		
January	0 8½	0 7
February	0 11	0 7½
March	1 0	0 8-66

The average price for the year of eggs 1½ozs. in weight and over was 11.802d. per dozen, as compared with 11.33d. per dozen for the year 1932-1933. The average price for 1½oz. eggs was 9.77d. per dozen.

PROFIT OVER COST OF FEEDING.

The average number of all eggs laid by birds under test was 140. This average is very low, being the lowest on record, and is probably due to a part to the revision of the conditions with regard to the weighing of the eggs, combined with the general unfavorable season for egg production.

Allowing for 75 per cent. to be first grade from a marketing point of view, that is, 1½ozs. and over, and 25 per cent. 1½oz. eggs, the return per bird was 10s. 11½d., and the cost of feeding 4s. 6d., leaving a profit over the cost of feeding of 6s. 5½d.

The following were the winning birds in each section:—

FINAL LEADING SCORES, APRIL 1st, 1933, TO MARCH 31st, 1934— FIRST GRADE EGGS ONLY.

Bruce Rowe, Two Wells (Barnevelder)	240	5/1/34	72	1	73

THE 1934-1935 TESTS.

To encourage further the official testing of stock, the Government erected an additional 258 single testing pens for the tests, and the following entries were received:—

White Leghorns.....	364
Cuckoo Leghorns.....	3
Black Orpingtons	75
Rhode Island Reds	25
Black Minorcas	12
Barnevelders	3
Langshans	3
Total	485

Front view of Competition Pens, showing the general design of pens, also feeding troughs on the doors.

Rear view of the Competition Single Testing Pens. There are 501 pens available for competition work. This view shows the watering system and ventilation. There is a space of 14ft between each row of pens.

SINGLE TEST EGG-LAYING COMPETITION, 1934-35.

DEPARTMENT OF AGRICULTURE.

SINGLE TEST EGG-LAYING COMPETITION, 1934-35.

Conducted at Parafield Poultry Station.

LEADING SCORES TO WEEK ENDING APRIL 28th, 1934.—FIRST GRADE EGGS ONLY.

SECTION 1.—WET MASH.

Class 1.—White Leghorns.

Singles—

	Eggs Laid.	Bird No.
C. T. Rodger	20	103
C. Guthridge	20	50
A. G. Dawes	20	205

Trios—

B. Cooke	53	319-321
J. C. Normandale	45	76-78
J. O. Marshall	44	85-87

Teams—

A. Young	82	61-66
Willowbend Stud Poultry Farm	80	474-479
A. H. Matthews	79	7-12

SECTION 1.—WET MASH—continued.

<i>Singles—</i>	Eggs Laid.	Bird No.
<i>Class 2.—Any other Light Breeds.</i>		
<i>Singles—</i>		
Langmaid & Bettison (Black Minorcas)	11	473
A. Heaysman (Cuckoo Leghorn)	9	332
A. Heaysman (Cuckoo Leghorn)	7	331
<i>Trios—</i>		
A. Heaysman (Cuckoo Leghorn)	21	331-333
Langmaid & Bettison (Black Minorcas)	12	471-473
<i>Class 3.—Black Orpingtons.</i>		
<i>Singles—</i>		
F. F. Welford	24	460
B. Cooke	22	387
F. F. Welford	19	458
F. F. Welford	19	375
<i>Trios—</i>		
F. F. Welford	59	458-460
B. Cooke	58	385-387
H. J. Mill	40	334-336
<i>Teams—</i>		
F. F. Welford	90	373-375 & 458-460
H. J. Mills	59	334-339
A. G. Dawes	55	340-345
<i>Class 4.—Any other Heavy Breed.</i>		
<i>Singles—</i>		
Woodbury Poultry Farm (Rhode Island Red)	21	407
A. G. Dawes (Rhode Island Red)	20	395
E. F. Snow (Rhode Island Red)	19	402

GRASS HAY COMPETITION.

SOUTH-EASTERN DISTRICT—SEASON, 1934.

(Judged by Mr. E. S. Alcock, Agricultural Instructor.)

DETAILS OF ENTRIES.

Position.	Name.	Address.	Suitability of Plants. 25	Curing. 25	Stage of Cutting. 15	Apparent Nutritive Value. 25	Storing. 10	Total. 100
1	Wookey, R. .	Robe . . .	24	24	14	24	9	95
2	Sims, I. . . .	Glencoe ..	23	24	14	23	8	92
3	Chambers, W. K.	Mil Lol ...	21	22	13	22	8	86
4	Fartch Bros..	Burrungule	23	20	11	20	7	81
5	Kemp, A. C..	Hatherleigh	20	20	12	21	7	80

THE WINNING ENTRY.

Mr. Alcock's remarks on the winning entry were as follows :—

A very good entry. The hay was cut from a fine paddock, comprising portion of a reclaimed swamp, in which Strawberry Clover, King Island Melilotus, Rib Grass, Black Medic and various grasses, including Perennial Rye Grass, were growing. The weather had delayed the carting, but nevertheless the material was in good condition, and except for being a little dry and brittle, had cured out to a fodder of satisfactory quality and colour. This hay had been cut before the grasses were too far advanced. It was well stacked and thatched with cutting grass.

MAIZE CROP COMPETITION AT MOUNT GAMBIER.

The following are the results of the maize crop competition judged by Mr. W. H. Downes (Dairy Instructor) and conducted under the auspices of the local Agricultural Bureau and the Agricultural and Horticultural Society :—

Competitor.	Variety.	Date Sown.	Date Judged.	Previous Crop.	Apparent Yield.	Germination	Cultivation and cleanliness.	Foliage and general appearance.	Evenness.	Freedom from Disease.
M. E. A. Kannenberg (3)	Ninety Day .	Jan. 6	April 21	Maize	(35) 25	(15) 12½	(15) 14	(15) 12	(10) 8	(10) 10
S. Norman.....	Hickory King	Oct. 23	Feb. 16	Grass	27	12	13	11	8	10
J. Hyde	Flat Red ...	Nov. 25	Mar. 1	Maize	28	11	14	9	7½	10
E. E. A. Kannenberg (2)	Ninety Day .	Dec. 13	Mar. 28	Maize	22	13½	14	10	8½	10
E. E. A. Kannenberg (1)	Hickory King	Nov. 22	Mar. 28	Maize	25	12	14	9	7	10

In commenting on the Competition Mr. Downes states:—"The foregoing results indicate the close nature of the Competition with a limited number of entries. The season was not an ideal one for the growing of green maize crops on account of the scarcity of rain during the principal growing period. Despite this fact, however, each of the entries was a well-grown crop, in every way worthy of competition. The winning crop, Mr. E. E. Kannenberg's No. 3 entry, consisted of an excellent stand of 'Ninety Day.' This was the final crop judged, and therefore secured some benefit from the March and early April rains. An excellent germination was secured, and the crop was of good medium height, with an abundance of slender stalks well covered with good green leafage and well-formed cobs. Cultivation was also very clean. Mr. S. Norman secured second place with a nicely grown crop of Hickory King. This crop was the first one to be judged in the Competition, so it probably secured less rain than any of the other entries. Its achievement in securing second position is all

the more meritorious. The fact that it was grown on land of practically virgin character, possessing a good sound subsoil, may have helped considerably. When judged on February 16th it presented a nice green appearance, with a few withered leaves. A crop of medium height, slightly uneven, which should yield well, but showed a little weed growth, chiefly 'fat hen.' A crop of Flat Red owned by Mr. J. Hyde occupied third position. This was of good height, and should yield well, though a little uneven. Cultivation was well done, and a fair germination had been secured, but the crop was commencing to wither badly on account of drying winds experienced and lack of rain. If anything, this crop was inclined to be a little coarse stemmed for grain fodder purposes. Mr. E. E. A. Kannenberg's No. 1 entry was a fair crop of fine-stemmed plants, but showed evidence of dry conditions in the withered condition of leaves. His No. 2 entry was in slightly better condition and germinated exceptionally well, but would yield poorly.'

PARAFIELD POULTRY STATION.

NOW BOOKING ORDERS FOR SPRING, 1934.

EGGS FOR HATCHING AND DAY OLD CHICKENS

WHITE LEGHORNS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, £2 per 100.

DAY OLD CHICKENS.—15s. per dozen; £4 per 100.

BLACK MINORCAS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, £2 per 100.

DAY OLD CHICKENS.—15s. per dozen; £4 per 100.

**Free on Rail,
Salisbury.**

**DELIVERY.—CHICKS—July to September.
EGGS—July to September.**

Intending breeders should recognise the importance of establishing their flocks with only the very best of stock also, pay particular care to the size of the egg. The future of the poultry industry in South Australia is almost entirely dependent on the export trade; the size of the egg for export is of the greatest importance. The breeding stock at Parafield is carefully selected and every egg set or sold is of a minimum weight of 2ozs., and a large percentage considerably over.

All Eggs and Chickens sold from Parafield Poultry Station are guaranteed to be produced at Parafield.

EARLY BOOKING IS ADVISABLE.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Flinders Street, Adelaide.

G. F. ANDERSON, Poultry Expert.

**“The wick may
be ‘starving’
...use *Laurel*, the Perfect
‘food’ for your Lamp & Stove”**

says the Laurel housewife

These pictures show flames after a 24-hour burning test. The lamp on the left burned Laurel. Note the steady flame, and the soft white light, without smoke, soot or flicker ! The other two burned so-called “cheap,” inferior kerosenes. Clogged by dirt and carbon they were **STARVED** for fuel, causing smoke and soot. Guard your wicks from **STARVATION** ! Insist on **LAUREL**.

Wise housewives always say

LAUREL

not just “Kerosene”

THE ADDITION OF TWO CRUCIFEROUS WEEDS TO THE LIST OF THESE PLANTS IN SOUTH AUSTRALIA.

[By WORSLEY C. JOHNSTON, R.D.A., Agricultural Instructor.]

INTRODUCTION.

During the inspection of a field of Canary Grass (*Phalaris canariensis*), two weeds of the cruciferous family were found. These were subsequently submitted to Mr. J. M. Black, who identified them as *Conringia orientalis* and *Barbarea praecox*, both introduced weeds. The former had not been previously recorded in this State.

As there appears to be reason to believe that either or both may prove serious agricultural weeds, it is proposed to give a short description of each, with any information that can be gathered as to their habits. The former of the two was found over the greater area, and it can be reasonably assumed that it has established itself as a naturalised plant in this country. The other plant has made its appearance over an area of approximately 90 acres. Admittedly, the number of specimens was very limited, but as it was found over such an area, it was only justifiable to assume that it had been there for several seasons. Because of the lack of ideal conditions of soil and climate it had not spread greatly. Whether in the future the plant will become acclimatised and then become widespread can only be proved by time.

***Conringia orientalis*.** (L.) Andrz. Hare's-Ear Mustard.

(Also known under *Erysimum orientale*. (L.) Miller.)

Description.—A free growing annual, reaching a height of 4ft. The young leaves form a thick tuft 3in. to 6in. in length; smooth, broadly oval, with a rounded tip, and tapering towards the base; edges almost entire, although the lower ones are slightly sinuate. The whole plant is covered with a glaucous bloom, similar to that on a cabbage. The young plants greatly resemble a cabbage. The branch leaves are thick, oblong, glaucous, resembling the shape of hare's ears. Those near the top of the branches are more clasping on the stem than those lower down the branch. The flowers are about 1in. in width, of a creamy-whitish color, borne on a short stem, which elongates as the seed pod grows. The seed pods are thin, smooth, and almost square in section, almost 4in. in length, containing upwards to 50 seeds, which are small and of a brown color. When they become wet they exude a gelatinous substance, which gives them the power to adhere to the feet of animals, or to the wheels of farm implements, a fact that has great possibilities in the distribution of the plant.

Origin.—This is an Old World species which, according to Georgia (1), has established itself in the wheat-growing states of America. It is also recorded from the north-west of Victoria.

Localities Where Found.—As far as can be ascertained, this plant has never been recorded in this State before, and at present it is only known on a farm at Hamilton. It is extended over a considerable area on this place, which only goes to show that it has been unnoticed for a number of years.

Its Agricultural Importance.—Local knowledge of the plant is very limited, and until it was pointed out to the landholder during a crop inspection it had not been realised that it was a new weed for the district or the State.

American experience appears to indicate that, if not held in check, this weed will materially operate against the possibility of growing satisfactory crops of any cereals, and so every effort should be made to control the plant while it is young.

Its free seeding habit, together with the adhesive power of the damp seeds, make it a plant beset with grave possibilities as to its rapid spread; hence a vigilant watch should be maintained for the weed, and every endeavour made to eradicate it.

Conringia orientalis. (L) Andr. Hare's Ear Mustard.

The palatability of the plant has not been subjected to any form of criticism, and local opinion has nothing to offer in this regard; but from the taste and smell of the leaves there does not appear to be anything to suggest that it would be obnoxious to farm animals. It must be borne in mind, however, that definite feeding tests have not been conducted.

Control.—As the plant is an annual, it would appear that much can be achieved in the way of control by the early preparation of each fallow. In fact, great care should be exercised to see that the field on which the weed is known to occur is broken up as early as practicable. In this way many of the young seedlings will be killed, but when shifting from one field to the next precautions are necessary to see that none of the seeds are adhering to the implements. In a general way the weed does not offer any greater difficulties than most of the annual cruciferous weeds.

The action of sprays will prove to be most disappointing, as the waxy nature of the leaves will shed all liquids very quickly, and thus any spray will not remain on the leaf for sufficient time to allow of enough absorption taking place.

Barbarea verna. Asch. Early Winter Cress.

Soils Suitable.—Local experience, as far as it goes, would suggest that the plant requires a friable, well-aerated soil for its maximum growth. It was significant that on the farm where the weed has occurred its greatest growth was found on the black soil patches, whereas any plants found on the red soils were much less robust—in fact, many plants in such soils were decidedly stunted in appearance.

Barbarea verna. Asch. Early Winter Cress.

This plant was recorded by Black (2) under the name of *Barbarea praecox* as having made its appearance near market gardens at Bridgewater. It is significant that the same author deleted the species from his later work. (3)

Description.—The plant is smooth, being devoid of hairs of any description. Leaves of a dark green, being divided into about eight lateral lobes, auricled and stem clasping. The flowers are large, and of a bright yellow color, about $\frac{1}{2}$ in. wide; seed pods very numerous, carried on thick short stems, about $\frac{1}{2}$ in. in length. The pods are about $1\frac{1}{2}$ in. in length, are stiff, and rather sharply four-sided. Seeds are numerous, small, and of a brownish color, rather flattened in shape, and covered with minute tubercles. The plant is given as a biennial or perennial by several authorities, but there is every reason to believe that, under the conditions of our agricultural areas, the plant has an annual habit.

Origin.—A native of Southern Europe, which has made its appearance in most temperate parts of the world.

Localities Where Found.—Other than the record of the species given by Black, there does not appear to be any further locality records for this State except the present case. The plant was found on a farm at Hamilton, where it was distributed over a considerable area. Previous records of it have been in such a situation as to suggest the escape from a garden, but in the present case there is nothing to give that impression. The plants were distributed over agricultural land.

Its Agricultural Importance.—The fact that this plant was recorded in 1909 by Black (2), and that in his later work (3) he saw fit not to record the plant, would lead one to the belief that the species does not find the climatic conditions of this State congenial to its rapid spread. It would seem that between 1909 and the present time there has not been any specimens of it taken. If this is so, there is no reason to have apprehension as to the agricultural possibilities of the weed. There is evidence to show that the species is grown in some parts of the world as a salad vegetable, a fact which indicates that there are no serious taints or flavours attached to the plant. There is every reason to believe that stock will find this plant palatable, and that under conditions where they have access to it there will be none of it to go to seed.

Control.—The careful cultivation of any land on which this plant has made its appearance seems to be all that is necessary to keep it in check.

Soils Favored.—From the limited amount of observation available it would appear that this plant shows a preference to the more friable types of soil. A few specimens were found on the red type of land, and in such cases the growth was far from robust.

DAIRY CONFERENCE, MILANG, MAY 9th, 1934.

DEHORNING—AN ASSET TO PRODUCTION.

[J. Y. HUDD, Adelaide.]

In these times when every man is trying to increase production, without increasing his herd and without increasing costs, most men have neglected the greatest asset in the business, namely, contentment of the herd.

During the last decade great strides have been made in the scientific feeding for production, in the mating of the right type of cattle of any particular breed, and rigid testing and culling of all animals that do not come up to a desired standard of production. We boast to-day of the lack of violence in our country; is it the result of education? More, I should say, it is the result of contentment instilled by education. We do not see men continually committing acts of violence, and it is safe to go anywhere within reason without fear of molestation. This is not so with our dairy herds. Confine them in any small area for only a short time and watch results; they very soon become a milling, horning, moving mass, the weaker and more timid animals becoming more and more agitated through fear. This state of nervous strain does not tend to improve the producing qualities of an animal.

Again, watch animals feeding in a field, especially if feed has been put out to them. The "bullies" in the herd immediately move from place to place hunting and disturbing those more timid than themselves. This tends against production, as the timid animals have to keep a constant watch against the horns of the aggressor, and be ever ready to run. Also, an animal that is more or less of a bully never milks up to expectations; she spends too much of the time she should be feeding in disturbing others. This breeds a habit of discontent, always wanting what some other cow has.

This matter of contentment is a thing that has to be given serious consideration in the near future. We have interfered in many ways with Nature, many of them to our advantage and some to our ill-content. When Nature made cows, she gave them horns for protection against other animals who were the natural enemies in an age when the law of the survival of the fittest was the supreme law. Man also at that time was governed in the same way, but in the course of enlightenment he has not applied the same laws to his cattle as he has to himself. No man to-day is allowed to assault his neighbour, much less use lethal weapons against him, or he is immediately put under restraint, and his weapons confiscated; yet dairymen allow this to be a daily occurrence among their dairy cattle, with a consequent loss of production.

It is said by some that horns are necessary to define a type, but cows give milk from their teats, not from their horns. At the 1933 Royal Show the champion bull in the Jersey Class was a dehorned animal; that does away with the argument that it spoils them for Show purposes. The hardest obstacle in this world to remove is tradition, and this is the main cause to-day why cattle dehorning is not more popular.

Now, let us deal with the most important article, especially in regard to the pure breeds, namely, the Herd Master. Many of these men—although they will not admit it—go in daily fear of their lives when dealing with the male animals of their breed. These men, because of their ability and knowledge, are a great asset to the Dairying Industry, yet how many of them have been cut off suddenly at the peak of their careers by a bull's horns? Before me as I write I have a list of Press cuttings of accidents, fatal and otherwise, during the last two years, and the list is appalling. Horns are not required in a country where wild beasts do not roam. Try and picture what would happen at the Royal Show parade if a rusty bull was to get away from his attendant and start looking for trouble?

[Papers Read at Conferences.]

We pay too high in risks in many ways, simply to see a nice pair of horns on an animal at Show time. No fence—especially in the country districts—is bull-proof, and an animal running in a paddock adjacent to a road is a potential menace to children and pedestrians if he has his horns on.

Then there is the loss which is sustained by cattle that are used for slaughter. Ask any butcher what his loss is through bruised meat, and it is tremendous. Our Trade Commissioner, Mr. McCann, in a recent article, stated that in the Argentine none of the exporting firms in chilled beef would handle an animal that had not been dehorned as a calf, and the dehorning of calves was a simple matter.

Increase production by adding contentment to your herds, which can only be done by removing the source of discontent, namely, the horns.

MANAGEMENT OF THE DAIRY HERD.

[A. KELLY, Milang.]

In these times of depression and low butter fat prices the management of the herd calls for a good deal of attention if one is to receive the best results with as little expense as possible. The bull—as is often said—is half the herd. The bull should be always in a yard or tied up, with a ring in his nose, preferably in a yard where he has more chance for exercise, which is absolutely necessary. He should be fed similarly to the cows. I feed chaff, with a change of sometimes bran, crushed oats, or a little linseed meal. These changes are relished by the bull, and have not had any injurious effects in keeping the bull fit and getting the cows in calf. He is also supplied with a salt lick, and an occasional sheaf of hay. One of the main reasons for keeping a bull yarded is that the services to each cow can be regulated, which in a large dairy herd with a young bull means a great deal to the life of a bull. One or two services to each cow is quite sufficient and does not harm the bull.

I advocate a pure-bred bull from high-producing stock of whatever breed the dairyman desires; he costs no more to feed and will raise the butterfat standard of the herd, which is the main factor these times.

As regards the cows, there is only one sound method by which to carry out dairying successfully—that is, the testing of all cows. This is the first matter of importance, for it gives some idea of how to feed the cows economically, which information is absolutely necessary. For instance, dairymen cannot afford to, nor is it right, that a cow giving between 100lbs. and 200lbs. fat a year should have the same ration as cows giving between 400lbs. and 500lbs. fat; hence the reason for testing. Once testing is started, each cow can, and should, be fed according to her production. Personal supervision may show that cows require a change of food to maintain high production, therefore I make a practice of always feeding chaff (hay feeding is too wasteful). For a change of food they have at different times crushed oats, bran, linseed meal, with a good supply of bone meal or super. A little salt in the food is helpful.

A cow should be mated to calve about every 12 months. I also find it necessary for a cow to have not less than six weeks, preferably eight weeks, dry. There is a wide difference of opinion regarding the best time for cows to calve. I endeavour to have some come in all the year. Of course, green feed is necessary, and should be grown as much as possible.

Dispose of the culls or low producers. Do not sell them just as soon as they are dry, but if sound, carry them on, put a little condition on them, and sell them with calf at foot.

To replace these cows, breed from the high producers and avoid going to the sale ring as much as possible. While there are some good clean cows obtained that way, there is always the possibility of introducing disease. If cows are urgently wanted, go to someone who is reliable and will recommend a cow, even if it costs a little more.

[Papers Read at Conferences.]

Calf feeding is most important, so far as the heifers are concerned, for these are the future herd. The best method is for the first week give whole milk, then after six weeks feed half whole milk and half separated milk. Do not over-feed; it leads to scours. Because of the low price of butterfat, this feeding is preferable to buying other foods. Calves should be kept on milk until about six months old, but should have chaff, or some long hay, as soon as they will eat. This has a tendency to keep a calf from scouring.

Regularity should be practised in dairying, both in milking and feeding stock.

To give some idea how the yield per cow can be improved by testing, culling, and feeding, I quote my testing figures:—In four years I have brought the lowest cow in the herd from 138lbs. to 324lbs. fat, average 241lbs., while the highest cow has risen from 352lbs. to 497lbs. fat, average 357lbs. By this method we have learnt if a cow is not worth feeding she is not worth keeping.

PASTURE DEVELOPMENT.

[E. L. GOODE, Narrung.]

When the extent of pastures and pasture production is considered, it is obvious that grassland studies, designed with a view to the improvement of the pastures, are of great importance. Of Australia's overseas exports something in the region of 60 per cent. in monetary value is directly derived from her grasslands. Similarly, of Queensland's and Victoria's exports 80 and 70 per cent., respectively, are said to be the products of grasslands in those States. These are striking figures when one realises the importance and variety of non-grassland products, wheat and other cereals, fruit and fruit products, metals, minerals, and manufactured goods. Any improvement in technique, which has as its design the more economic production of wealth from a given area of grassland, must reflect itself, therefore, upon national well-being.

There are four main avenues along which attention must be directed, namely, those of species, strain, soil fertility, and pasture management.

The strain work on pasture plants which is being conducted in Australia is of a most encouraging kind. Critical trials with various forms of Rye grass, Cocksfoot, *Phalaris*, Lucerne, and Subterranean clover, and many other species are under way.

It is probable that the acreage of the class known as "improved pastures" could be added to considerably if seed representing more suitable strains were available.

There is evidence in Australia of the success which has attended the initiation of the New Zealand Rye grass seed certification scheme. Trials have shown that Perennial Rye grass of a good pasture type can be grown over an extremely wide range of conditions in Australia. The requirements looked for in high class pasture strains are the abilities to withstand a series of successive dry summers, to make vigorous growth with the advent of autumn rains, and to maintain a high standard of production throughout the rest of the year. Other grasses, such as cocksfoot, *Phalaris tuberosa*, Wimmera Rye grass and *Paspalum* are being widely sown and tested in many parts of Australia.

CLOVERS,

The value of clovers as a constituent element of pastures is well recognised. They not only enhance the general fertility of the soil, improve its texture and darken its colour, but in so doing they indirectly improve the growth of the grasses growing in association with them. This is particularly true in regard to those grasses which require a reasonably high standard of soil fertility—grasses that in general are the more valuable among our grazing plants. The clovers are, furthermore, richer in food materials than are the grasses; not only richer in proteins, but also in many essential minerals.

The grasslands of Australia are deficient in minerals, and it is interesting to note that when soil and other conditions become conducive to the growth of clovers, mineral deficiency quite often becomes corrected, at least in so far as evident symptoms in

[Papers Read at Conferences.]

the health of stock are concerned. An adequate proportion of clover in any pasture must be regarded as being essential to the well being of the grasses in that pasture as well as to the health of the livestock that browse upon it.

It has been estimated that some 4,500,000 acres in Australia have been sown with introduced pasture plants. While this acreage only represents about 0.25 per cent. of the total area of the Commonwealth, it forms, however, an important proportion of the country on which dairying is being conducted. Any improvements of this nature would need to be accompanied by the maintenance of adequate soil fertility, correct pasture management being equally important.

Well planned research work on pasture problems is essential, and it is the cheapest way in which the community can gain new knowledge, ultimately to be put to economic advantage.

THE IDEAL PASTURE.

This should contain an admixture of grasses and clovers—a leguminous content is important in any pasture, it is essential in dairy pastures. Legumes serve a second useful purpose in Australian grasslands, namely, they increase the soil fertility. A profuse growth of pasture legumes, such as that usually associated with a dense cover of well manured Subterranean clover builds up soil condition so that it is made more conducive to the growth of high grade perennial pasture plants.

The ideal dairy pasture is one where high production perennial grasses and clovers are dominant.

For the profuse growth of legumes on Australian soils the application of phosphatic manures is essential. There are many examples where nitrogen, lime, and potash have given good results.

SOIL FERTILITY.

The upbuilding of soil fertility is of particular significance on a number of Tasmanian soils where, in the past, there has been a long continued drain upon plant

COMPARE YOUR COSTS!

[Papers Read at Conferences.]

foods in the soil under a system of farming which involved the removal of a succession of cash crops. This has taken place without adequate or any regard being paid to soil replenishment.

The fertility of these soils has therefore undergone depletion, and means will have to be found to make good the deficiency. The Tasmanian Department of Agriculture during recent years has encouraged the growing of leguminous crops, and the practice is spreading throughout the dairy districts of the State. As a factor likely to influence the rate of improvement in pasture standards this practice is to be commended from every angle.

The principle of all fertility upbuilding per medium of clovers is sound. There are extensive areas in South Australia, particularly in the Adelaide Hills and in the South-Eastern portions of the State, where intensive development of sown pastures is proceeding. The use of Subterranean clover, together with superphosphate, has provided the key to this development.

Improved strains of Perennial Rye grass and *Phalaris tuberosa* must play an important part in the further improvement of existing sown grasslands in this State.

EXPERIMENTAL WORK.

There is evidence that high grade permanent pastures can be profitably developed under irrigation. The experiments of the Waite Agricultural Research Institute, near Murray Bridge (Wood's Point), have shown that improved strains in the perennial grasses are extremely useful elements in irrigated pastures. The use of those strains will help to keep the clovers in check and is calculated to improve the balance of grasses and clovers in the pastures. Considerable difficulty has been found on those pastures because the proportion of clover has shown a tendency to become too high, and this has made efficient grazing difficult because of the danger of bloating in livestock.

A recent inspection by the South Australian Committee of the Australian Dairy Council was made at Greenock, where fields of Perennial Rye grass and Subterranean clover had been sown. Here 31 cows and heifers had been grazing for nine months, and evidenced that rapid growth was made after the first rains by the Rye grass, and this pasture could be sown with confidence on a 20in. rainfall.

At Eden Valley were four plots sown with various grasses and clovers, but the opinion expressed was that the Perennial Rye grass and Subterranean clover was the best pasture—a herd of 18 Shorthorn cows was quite unable to cope with the feed; an interesting demonstration of what top dressing will do on natural pasture was seen here, where a field of 14 acres was dressed at the rate of 90lbs. of superphosphate to the acre for three years, during which period not less than 60 sheep has ever been carried on it, and at the time of inspection there were 114 sheep in the field, all of which were in good condition, and the feed, chiefly Subterranean clover and Soft Brome, was, if anything, too rank. The application of sulphate of ammonia had decreased the Subterranean clover pastures to a minimum, but had in the early stages of the experiment assisted the Rye grass.

The general opinion seemed to be that the most economical fertiliser to use was a good grade superphosphate applied at the rate of 1cwt. to the acre. A crop on a very light soil was inspected at Mount Pleasant on which only Subterranean clover appeared to flourish, and it is expected that by enriching the soil with this other grasses will be established.

At Mount Barker a field was inspected consisting of four paddocks, each 2½ acres, sown with various mixtures, Perennial Rye grass, White clover, Subterranean clover, *Phalaris tuberosa*—all fields were dressed annually with 2cwt. superphosphate per acre, and two of the plots received an application of sulphate of ammonia. From September 1st to October 1st 22 cows were carried for four hours a day on the

[Papers Read at Conferences.]

pastures, being placed in a different field each day, so that each plot was fed off every four days, and later 24 cows were carried to November 24th, at time of inspection. It was noticed that the fields dressed with sulphate of ammonia showed less growth on the clover; and it was thinner than those dressed with superphosphate only. All the pastures were in splendid heart, as also were plots inspected at Bugle Ranges and Shepherd's Hill, where excellent fields of clover were seen just on the border of heavily timbered forests.

For local conditions on soil around the Lakes, as at Narrung, lucerne holds pride of place; sown at the rate of 4lbs. to 5lbs. per acre, with a cover crop of oats or barley at the rate of ½bush. to 1bush. per acre, splendid results have been obtained. It has been found necessary to cultivate the pastures when established with a tine cultivator, dress with 90lbs. to 1cwt. superphosphate, and sow with oats or barley at the rate of not more than 1bush. to the acre every other year. The addition of cereals improves the growth of lucerne rather than otherwise, and a good mixed hay for cows is obtained. Too much stress cannot be laid on the value of the cultivator, drill, and harrows on lucerne pasture. This does almost as much good in opening up the soil to the plants as does the action of superphosphate in forcing new growth.

[Portion of report to Australian Dairy Council by Mr. J. Proud, Manager of the Camperdown Cheese and Butter Factory, and Mr. A. E. Sweaney, Manager Inverell Co-operative Butter Factory, N.S.W.]

PASTURES AND THEIR MANAGEMENT.

There is no doubt that the basis of the great wealth of the Dominion lies in the scientific management of the pastures. From these an almost incredible return is yielded, due to top dressing. In general, the country was, in its virgin state, of very poor character. Thousands of acres possess but a few inches of soil on poor pumice formation, and on this originally grew ti-trees and bracken fern. Nothing could be more uninviting. These conditions also obtain in the famous Waikato district, where as late as 20 years ago land could not be sold for £1 per acre. Now such land could not be bought for less than £50 per acre, the returns being so phenomenal. This transformation has been effected by the application of fertilisers in the form of top dressing, which has clothed the land in excellent permanent pastures. These consist of Rye, Cocksfoot, Prairie, Fescue, and White clover. Up till quite recently it was thought essential to plough the pastures periodically, and after taking a crop off the land to relay in pastures. This has since been proved a fallacy. The cropping of dairy land has become obsolete, the new science of grassland farming succeeding it. It is now found that a permanent pasture can be maintained at its highest state of perfection by top dressing with fertilisers and the hard use of chain and tripod harrows. It is also claimed that, when the pastures cannot be grazed short enough to prevent any suspicion of running to seed, the mower should be employed. Research concerning pastures has proved that their highest value of milk production is in the young grass shoots which are high in protein content. Consequently, pruning by short grazing, harrowing, and mowing is essential. Evolution is likewise taking place in the methods of top dressing. Until quite recently the system was to top dress the pastures of the entire farm in one, and later in two, annual applications, viz., in early autumn and early spring. Such a course produced an excessive growth in the spring and early summer months which could not be grazed down. Thus a considerable amount would run to seed and not only lose its highest nutritive value as feed, but also have a damaging effect on the pasture land. To obviate this the modern system is to top dress the paddocks in rotation and likewise graze them. In this way they obtain and utilise the maximum nutritive value of the pastures. Superphosphate and smaller amounts of basic slag are the universal fertilisers, and are used at the rate of from 2cwts. to 4cwts. per acre per year. The fertilisers cost 5s. per cwt. at the farms. Broadcasting from the back of a motor lorry, where the machine is connected

[*Papers Read at Conferences.*]

and worked from a sprocket on the back wheel, is the latest and quickest method of spreading. It is a significant fact that the application of superphosphate on any of the land immediately encourages the growth of clover. While none is sown with the other grass seeds all pastures are well stocked with it. In fact, it is so superabundant that experiments are being made with mixtures of nitrate of soda and other nitrogenous manures with a view to curtailing its growth in the pastures south of Auckland.

In the north of Auckland Province *Paspalum* is the staple pasture, and the superphosphate top dressing of it, likewise, stimulates clover growth, which is, however, most desirable in this pasture. We were supplied with the returns of one North Auckland dairyman, who, on a 60-acre farm of *Paspalum*, produced 20,000lbs, butter from 60 cows during last season. As quite a considerable amount of Australian butter is produced from *Paspalum* pastures, where in many cases the clover is gradually dying out, we wish to emphasise these results in the hope that top dressing will be employed, believing that like results can be obtained here.

So universal is pasture management as above described, and so much faith have they in its ability to carry them through even a severe winter, that it is not surprising that we were unable to find any supplementary winter crops. In fact, we rarely saw an acre of ploughed ground throughout the whole tour. A noteworthy feature in the Dominion is the general adoption of hedge fences. These serve the dual purpose of protecting stock and pastures in bleak weather, and add much of the picturesqueness to their rural scenery.

THE CARE AND MANAGEMENT OF CREAM AND DAIRY PRODUCE.

[J. M. YELLAND, Milang.]

In the production of first class butter it is necessary that great care and attention should be given to all details in connection with the article produced, from beginning to completion. In order to do this it is very necessary that all participants should have a knowledge of their part of the business, so that a complete circle of efficiency may be obtained. Before the salesman can sell the butter the manufacturer must produce a first class saleable product. Before the manufacturer can produce a first class product the raw material must be of standard quality. Hence, in reality, the marketing of butter depends as much on the man who produces the cream as on the man who manufactures and markets the butter. It is also necessary that a knowledge of the needs of each unit of the industry should be acquired in order that it should be maintained at a high level. Let me deal with each as briefly as possible.

THE DAIRYMAN'S RESPONSIBILITY.

He should be clean, careful, and thoughtful in his work. His premises, including cowyard and separator-room, should be kept as clean as possible. The buildings should be of stone, iron, or sawn timber, with an iron roof; the manger and bails of sawn timber, so that they can be painted and, if necessary, washed or whitewashed. The floor should be cemented and have a slope of about 1 in 30. Plenty of ventilation should be in evidence, as fresh air and as much sunlight as possible are the best known bacteria destroyer.

The utensils, such as separator, cans, buckets, &c., should be well washed in plenty of hot water and then thoroughly drained.

The cows' udders should be well washed and wiped. It is necessary to have in each bail a utensil—a half-gallon galvanised dipper is most suitable—containing a good cloth and warm water, or preferably a weak solution of Condyl's fluid.

The most important part for which the dairyman is responsible is the care and attention he gives to his cream. Separate at about 44 to 46 test. The large percentage of milk present in thin cream accelerates the action of the harmful bacteria, thus

[Papers Read at Conferences.]

causing premature staleness. The cream should be cooled as quickly as possible and kept at a low temperature. This also is necessary to retard the action of harmful bacteria. It is best to stir the cream daily, and on no account should warm cream be mixed with cold.

Deliver to the factory as often as possible. The present system of motor vehicles running around the country carting the cream long distances is both expensive and injurious to the quality of the cream. This will be rectified when the dairyman has sole control of his products. It is encouraging to know that cream suppliers are organising in this direction. As soon as the industry is placed under one large co-operative control, South Australia—in which choicest butter constitutes less than 30 per cent. of her total butter production—will be able to raise her standard to equal that of the Eastern States. The difficulty, however, is that the cream supplier has become apathetic; his position seems hopeless, and he has lost confidence in the manufacturing and handling of his products, and that confidence, under present conditions, can never be regained.

After the cream has been delivered to the factory in good condition, the onus of responsibility rests with the manager. We now have a considerably higher standard of efficiency in factory management than previously. All managers have to hold a certificate in grading, testing, and butter or cheese-making. This naturally gives a better opportunity of competing with other countries in the disposal of our products.

THE MANUFACTURING OF BUTTER.

At the receiving platform, after taking delivery, the cream is weighed and entered into the cream book. It is then sampled by placing the sampler from the top to the bottom of the cream; the reverse action to that of a pump is applied—that is, the barrel, not the plunger, is moved. This action takes a representative sample, but seeing that the sample is taken from top to bottom, beware of that milk which may have settled in the concave at the bottom.

[Papers Read at Conferences.]

The cream, after being sampled and graded, is tipped into a sieve. The cream having been tipped into a neutralising vat, is mixed with the addition of water, by means of rotating coils, as the butterfat content is too high for churning purposes without the addition of water. A test is now taken to determine the amount of lactic acid present in the cream. A specified amount (9 c.c.) is drawn into a pipette and blown into a white cup, and a few drops of phenolphthalein indicator added. A graduated burette containing 1/10th solution of caustic soda is filled to the "O" mark and the solution is allowed to drip into the cream until the caustic soda has neutralised the lactic acid. This indicated by the phenolphthalein colouring the cream a faint pink. The burette is read to ascertain the percentage of acid present in the cream. A chart is then consulted which specifies the amount of sodium bicarbonate in pounds and ounces, necessary to neutralise to a certain extent the acid contained in the full quantity of cream present in the fat. The whole of the acid is not neutralised, as this would affect the flavor of the butter. After neutralisation has taken place the cream is pasteurised. This particular operation has been accused of robbing butter of its old-time flavour; it certainly has robbed it of a lot of impurities. If this purification had not been wanted, money would not have been spent in this direction.

Pasteurisation consists of heating milk or cream to at least 140° F. for not less than 10 minutes to destroy bacterial life. The heating is followed by rapid cooling to check spore-formation. The temperature to which most factories raise the cream is between 190° and 200° F. Most food flavours are vaporised and pass off in the steam, and also most of the bacteria are destroyed. Care must be taken not to scald the cream, thus imparting a "cooked" flavour.

The cream is then subjected to rapid cooling known as the "shock principle." This is attained by allowing the cream to gravitate over coils which have first the ordinary water flowing through them. Next it passes over the brine coils of temperature about 20° F., and finally over the ammonia expansion coils to further reduce the temperature, and by regulating the flow of cream it is possible to freeze.

It is then pumped into holding vats and held at a desired temperature for several hours to ripen. This is an improvement on the results achieved by Pasteur when he first employed pasteurisation.

After the cream has been ripened it is ready for churning. The temperature for this can be lowered if necessary. The churning is usually done at approximately 45° F. Before the cream is passed into the churn, the latter is scalded and cooled. The cleanliness of the churn is the greatest difficulty, as it is made entirely of wood, having crevices in the joints, which would be a breeding ground for bacteria and mould. Mould is the biggest trouble in wood, and to counteract it, "chlorize," a disinfectant and germicide, is used. This has no effect on the flavour of the butter.

The cream is churned until it changes into butter granules and buttermilk. Care is exercised to have the granules about the size of corn. All the buttermilk must be allowed to run off as the retaining of any of this may leave mottles in the finished article.

The butter is then thoroughly washed in water of temperature of about 40° F., to eliminate any remaining buttermilk. Salt is then added in the proportion of 2 per cent. and the butter is worked to cause the salt and moisture to be incorporated in it. Government restrictions allow only 16 per cent. moisture in butter, so that care must be exercised not to exceed that amount.

The scoring of butter is as follows:—

A second grade butter made from cream grading 36, 37, 38 points would, if the manufacture were perfect, grade as butter 86, 87, 88.

First grade butter made from first grade cream would be 89, 90, 91.

Choice would be 92 upwards.

THE HAY ITCH MITE, *Pediculoides ventricosus* (Newport) (Acarina, Pediculoididae) IN SOUTH AUSTRALIA.

[By D. C. SWAN, B.Sc., Waite Agricultural Research Institute,
University of Adelaide.]

I. INTRODUCTION.

During the past few years reports have reached the Waite Institute from various sources of a skin affection occurring amongst workers handling certain agricultural products, notably grain, hay, and chaff. The trouble manifests itself chiefly as an irritating itch, and the information which has been obtained indicates that it is widespread. Its association with these farm products has been long recognised by farmers, as the term "hay itch" is well known in the agricultural areas of the State. The occurrence of "hay itch" appears to be due to the presence of a minute mite (*Pediculoides ventricosus*) in the materials. The mite, which is an ectoparasite on the larvae of many insects, may be present in very large numbers.

Fig. 1.—Time taken from the birth of a female mite until it produces young, in relation to temperature. Derived from data given by Webster (1910), p. 22.

An account of observations and experiments which have been made on this subject are presented in the present paper.

II. THE EXISTENCE OF *P. ventricosus* IN AUSTRALIA.

In South Australia "hay itch" has been usually reported after operations which involved the handling of hay taken from stacks a year or more old. In May, 1932, in consequence of such reports, samples of hay were obtained from several localities near Adelaide. Each lot of material was beaten out, and the resulting dust examined under the binocular microscope. In several cases a small mite was found in considerable numbers, which proved to be *Pediculoides ventricosus* (Newport). This mite has not been reported previously from Australia, though H. Womersley, now Entomologist at the S.A. Museum (unpublished data),

isolated it for the first time in June, 1931, from chaff being loaded on to a ship at Fremantle, Western Australia. This cargo came under notice due to an outbreak of dermatitis among the humpers who were engaged in handling the material. In Western Australia an itch of workers engaged in chaff-cutting operations has long been known in the cereal belt. The writer has been informed that this is also known to occur in the Eastern States. The only reference in the literature to the presence of the mite in Australia is in a note by Strong (1922), commenting on a communication by Hone (1922). Hone discussed "A series of cases closely resembling Typhus fever" in Adelaide, of which pathogen and vector could not be decided, but a relation with weevils and weevil-infested wheat was indicated. Strong's suggestion that *P. ventricosus* might be the vector of the infection, was inferred from the account given by Hone; the presence of the mite was not demonstrated.*

III. OCCURRENCE OF *P. ventricosus* IN OTHER PARTS OF THE WORLD.

Pediculoides ventricosus has been long associated by various authors with the occurrence of an itching, urticarial rash in man. The mite has been reported from many European countries, particularly those bordering the Mediterranean Sea. A number of references to it occur in British medical literature. It was recorded from the United States early in this century in association with a number of widespread cases of itch of the human skin.

Goldberger and Schamberg (1909), working in U.S.A., reproduced the symptoms experimentally by applying mites to the skin. They showed that dust from straw was not, in itself, capable of producing the itch. Webster (1910) reviewed the position in the United States, and Willcocks (1914) discussed it in relation to Egyptian cotton seed, in view of a skin affection occurring amongst London dock laborers engaged in unloading certain cargoes of this commodity. More recently the mite has been recorded in association with dermatitis of dockers, mill-workers, and agricultural labourers in various countries (England, France, Italy, Germany, Rumania, Algeria, Morocco).

IV. BIOLOGY OF *P. ventricosus*.

Pediculoides ventricosus is normally an ectoparasite of the larvae and less commonly of the pupae and adults, of a number of insects, particularly those which attack certain crops and stored products. Thus "boll-worms" are its usual hosts in cotton. It may occur on insects in the field. Newport's original specimens were found in the nests of an Anthrophorid bee, attacking the larvae. In Australia, as in parts of U.S.A., the larvae of the Angoumois Grain Moth (*Sitotroga cerealella*), a world-wide insect, is apparently the chief host. The larvae of this moth feed in the grains of various cereals, either in store or in the ear. They eat out the interior of the grain, and pupate within it, the adult moth emerging through a hole in the side; in haystacks, the grain in the ripened ears of the hay provides favourable food. Temperatures of about 80° F., and high humidity (up to 80 per cent. R.H.) are very favourable for the development of the moth, and large numbers rapidly develop under these conditions. In a haystack such conditions often occur. The mite when present in these situations attacks the larvae, and rapidly increases in numbers, as a result of the favourable environment and adequate supply of food (hosts). Mites of succeeding generations move through the material in search of fresh hosts, and persons handling it may become infested

* Mr. Womersley has kindly drawn my attention to a record of the genus *Pediculoides* by Rainbow (1906) who lists *P. alastoris* Frogg., a species from N.S.W. Froggatt (1894) describes this species as *Heteropus alastoris*; it was found attacking the larvae of the Eumenid wasp *Alastor* (= *Paralastor*). Froggatt's description of this mite is purely formal, and contains no details of critical value. From his remarks upon the mode of its occurrence it seems very probable that the species was *P. ventricosus*.

with mites. The rate of development of the mite, in relation to temperature, is indicated in the accompanying graph (Fig. 1) drawn from data given by Webster (1910).*

In haystacks the mite is commonest during hot summer weather. The unfed female succumbs rapidly in the absence of a host when the humidity is low and the temperature high, usually living only about one day. In low temperatures (less than 20° C.) it can survive much longer without food.

Fig. 2.—*Pediculoides ventriosus*. Non-gravid female. The broad basal portions of the chelicerae (mandibles) and the anterior part of the two tracheal trunks, are shown by broken lines.

The fact that the mite attacks various pests of agricultural products has been investigated with reference to its possible value in controlling the numbers of these insects. Evidence in support of significant control is lacking. The position is reviewed by Willcocks (1914) and Herfs (1926).

* The data are not presented by Webster in sufficient detail to allow of the complete velocity curve of development being given.

V. LIFE HISTORY AND HABITS.

The general details of the life history are well known (Webster, 1910; Willcocks, 1914; Berlese, 1925; Herfs, 1926). The writer obtained a supply of mites from an infested stack in 1933 and was able to breed them in great numbers in the laboratory. The following details are derived from observations made upon this material.

The life history is one of the most remarkable occurring in the Acarina. Both males and females are produced viviparously, and are sexually mature at birth. The female mite at this time is very small, measuring 0.25 mm. (1/100 inch).

Fig. 3.—*P. ventricosus*. Male. Note difference in chaetotaxy compared with the female, also modification of the hind legs as claspers. The external genital structures are ventral in life.

After fertilisation by the male, which occurs immediately after birth, the female seeks out a suitable host (in our conditions a grain moth larva), pierces it with its needle-like mouthparts, and begins feeding immediately. Before feeding it is slender and widest at the middle (Fig. 2). It is the developments subsequent to the commencement of feeding that make the life history so unusual. The mite feeds by sucking the body fluids (blood) of its insect host, with the aid of a well-developed pharynx. Shortly after sucking begins, a slight swelling is seen, almost at the tip of the abdomen of the mite. (Fig. 6.) This increases in size until it becomes globular. At first the mite is able to move about, but eventually the abdomen becomes so distended that movement becomes impossible. The mite then remains at one place on the surface of the larva, and continues to engorge; the abdomen develops into a glistening sphere which is visible to the unaided eye. Ultimately this sphere may attain a diameter of more than a millimetre (Figs. 4, 5, 7). The process is reminiscent of the engorgement of a tick with blood. The rate of engorgement depends on the prevailing temperatures. It takes less than a week at temperatures above 90° F., but may take two weeks or more at

lower temperatures. The eggs of the mite develop within the swollen abdomen and the embryos may be seen through the delicate chitin. The developing young complete their immature (nymphal) stages while within the parent, and are not born until they are fully mature.

The birth process is complex. The first young produced are males; only a small number are produced by any one female (3.6 per cent. of the progeny, Herfs 1926). The writer has not made quantitative studies, but my observations agree very well with those reported by Herfs. The males feed very little and pierce the parent sphere in order to obtain food. They are shorter and broader than the female, and more convex dorsally (Fig. 3). Their movements are slow and deliberate, and they do not leave the spherical body of the mother, but remain in a cluster around the genital aperture. (Fig. 4.) They fertilize the female mites as soon as the latter are born. Females are produced at a rate which varies with the temperature. At higher temperatures it is greatly accelerated. If the

Fig. 4.—Camera-lucida sketch of a gravid female, showing four males grouped around the genital aperture.

food supply is adequate, a female engorges to a size often greater than 1mm. before young are produced. Where a great number of unfed females attack a single host larva they may develop to a much smaller size due to shortage of food. Some individuals may be dislodged from the host when only partly engorged, and their cumbersome shape and weight prevents them from regaining a feeding place. With these individuals, young are still produced, the numbers necessarily being much smaller. In fact, any slight engorgement appears sufficient to enable some young to be produced. The number of young produced by a full-sized gravid female varies from 200-300 (Webster, Herfs). The process is spread over a period of a week or more. At the end of that time the abdomen becomes collapsed and transparent, due to the loss of its contents. The body of the parent mite retains its vitality throughout, which is evidenced by the continued movement of the legs.

The newly-born females at once begin their search for a new host. They progress in a characteristic fashion. The forelegs are chiefly sensory in function, and play little part in locomotion; walking is practically quadrupedal, being performed almost entirely by the second and third pairs of legs; the hind legs are dragged rather stiffly behind, and are of little assistance in walking. The general effect is an awkward and automaton-like movement.

The mites readily swarm over a larva placed with them, and make attempts to feed immediately (Fig. 6). A firm grip of the surface of the host is taken with the legs, the "head" is then lowered, the mouthparts being forced into the host, sometimes with perceptible effort. If the host is an insect larva, it reacts quickly to their presence, wriggling frantically, but the mites hold on tenaciously. If a number of mites attack a single larva, it may become immobilized in about 24 hours; with few mites the period is longer. At first the mites feed at random, moving on from time to time. No mark is left at the seat of the bite. When the end of the abdomen has become so much distended as to make movement difficult, the female completes its engorgement without moving to a new site. If the infestation of the host larva is heavy, it becomes almost obliterated by the mass of swollen mites, and ultimately shrivels, owing to the loss of its body fluids. At this stage it presents the appearance of a bunch of grapes (Fig. 7). With the commencement of the next generation of mites, such a collection presents an animated appearance, each sphere supporting a group of males, while unfed females swarm in all directions. An infestation as dense as that illustrated in Fig. 7 is probably unusual in nature.

VI. METHODS OF BREEDING THE MITES.

Two methods of breeding the mites were used. For food supply the larvae of the grain moth (*Sitotroga*) were employed. In the first method a quantity of wheat was placed in a phosphor-bronze gauze cylinder (3½ in. diameter x 3½ in. high), which stood in a large petri dish. The inside face of the wall of the petri dish was greased to prevent the escape of mites. The cylinder was closed by a sheet of glass, which fitted closely. A number of grain moths were introduced and allowed to oviposit. When their larvae were well established in the wheat, a number of non-gravid female mites were added. The apparatus was kept in an incubator at 26° C., and at a humidity of about 90 per cent., this being maintained by a large tray of water placed on the floor of the incubator. After about a week numbers of young female mites were produced, which swarmed on the sides and glass top of the vessel. This method was useful when large numbers of the moth larvae were needed, to provide a stock culture of the mites.

For observations on details of the biology of the mites, single grain moth larvae were dissected out from wheat grains. They were confined in small (½ in. diameter) solid watchglasses, of a kind which may be stacked into nests. In these the mites readily attacked the larvae, and a number of generations occurred, provided larvae were added from time to time to maintain the food supply. The cultures in these vessels could be examined readily under the binocular microscope.

VII. MOUTHPARTS OF THE FEMALE MITE.

The mouthparts are exceedingly small. When a female mite is feeding on the surface of a moth larva, the capitulum (group of mouthparts) is pressed against the surface of the host. No external sign of stylets can be detected during the process even when watched under high powers of the binocular microscope. When mounted on a slide, some individuals exhibit a slender, needle-like structure which protrudes from the tip of the rostrum. After straining with pieric acid and mounting in glycerine jelly, several mites were squashed by pressure on the coverslip. In some cases it could be seen that this structure consisted of a pair

of stylets which are the distal ends of the chelicerae or mandibles. These structures widen out within the body to form greatly swollen bases (Fig. 2) to which protractor and retractor muscles are attached. The palps are vestigial; their functions are served by the forelegs, which are used to palpate surfaces on which the mite is walking, before feeding is attempted. It may be noted that a short clubbed seta (? sensory) is present on the two distal segments of the fore-legs. No trace of a hypostome could be detected, and it is assumed that the chelicerae are the only piercing structures. The mouthparts are too small to lend themselves to any of the usual methods of dissection. It appears that the two chelicerae enclose a suctorial groove, as they are very difficult to separate. This would account for the ability of the mite to pierce the human skin sufficiently

Fig. 5.—Partly engorged female mite. It will be seen that distension is confined to the tip of the abdomen.

deeply to allow of a venom being injected into the hypodermal layers. One function of this secretion, as already indicated, would appear to be to immobilize the host insect larva.

VIII. OBSERVATIONS ON CERTAIN STRUCTURAL FEATURES OF THE MALE AND FEMALE *P. ventricosus*.

It may be noted that the drawing of the non-gravid female given in Fig. 2 differs in various particulars from all the previously published figures that have been seen by the writer (*e.g.*, Webster, Willcocks, Berlese, Ewing); it is widely different from that of Laboulbène and Mégnin (reproduced by Brumpt, 1927). No two figures agree, the chief divergence lying in the number of dorsal setae shown. It is usual to show two pairs of large setae near the base of the second pair of legs.

In my specimens only one pair was constantly present. The male has been also figured in a variety of ways by different authors. The drawings in the present paper were made with the help of the camera lucida from specimens mounted in Berlese's medium, using apochromatic objectives and compensating oculars.

Just posterior to the fore-legs, the cephalothorax bears a pair of club-like, pseudostigmatic organs, presumably sensory in function. They are bladder-like, with one side pushed in, forming a concavity which disappears on mounting in Berlese's medium. The spiracles are paired, opening ventrally between the bases of the fore-legs and the mouthparts. The tracheal system runs backward as a pair of tubes. These branch profusely in the abdomen of the gravid female, where they may be seen as conspicuous structures running meridionally.

IX. RELATION OF *P. ventricosus* TO MAN.

Reference has been made in an earlier section of this paper to records of the association of the mite with certain skin affections in man. *Pediculoides ventricosus* may, in Australian climatic conditions, attain large numbers in local favourable situations. This may occur in haystacks, produce stores, &c. In the work of handling hay infested with these mites, some may reach the human body and pierce the skin. This action will be most marked in hot weather, when their need for moisture is most urgent. The writer made three visits to an infested stack to obtain mites. This was done by pulling out well-buried sheaves and beating them out. After the first visit evidence developed on the skin of 14 bites having been received (max. temp. 80° F.); after the second, 2 bites (max. temp 60° F.); and after the third, about 30 bites (max. temp. 110° F.). The amount of exposure in each case was roughly the same, and the visits were all within the midsummer period.

All parts of the body are liable to be affected. Individual susceptibility to attack varies greatly (Larson, 1925). Some of the more severe cases reported (Webster, 1910) relate to persons who had slept on infested straw mattresses, the back and sides of the body being particularly affected. The body, arms, and neck are the usual regions where the mites bite. The face may be attacked, particularly the eyelid, upper or lower, and puffiness of both lids may result. The author was troubled with occasional bites in this region in the laboratory. It transpired that mites were escaping from cultures, climbing a binocular microscope that stood upon the bench, and running round on the eyepieces, from which individual mites readily transferred to the eyelids, when the microscope was being used.

Man is not a normal host of the mite. It does not persist long on the human body (Askins 1924) nor burrow under the skin (Askins, *loc.*). I have not seen any desire to burrow on the part of mites placed on the skin of the arm and observed under the binocular microscope. The anatomy and biology of the mite indicates that it does not burrow.

Asthma and dermatitis of workers in an Italian grain mill were traced to the mite (Ancona, 1923). The mill was infested by the moth *Tinea granella* L. Dermatitis was produced also amongst the inhabitants of nearby houses by dust from a mechanical elevator, at an English dock where barley from Morocco was being unloaded (Thompson, 1925).

Clinically, parts of the body affected by the mites exhibit a skin eruption. The following details are derived in part from the literature and in part from observations made by myself. The wheals vary in size and form with different subjects. They present, especially after rubbing, a raised whitish area with a small central vesicle, which marks the seat of the puncture. The blanched area is surrounded by a rosy red areola. The lesions may itch severely, especially when warm in bed, or

when the body is heated by exertion. Rubbing and scratching usually breaks the central vesicle and the possibility of secondary infection then arises. Itching usually subsides in 2-3 days, but the marks may last longer.

The following tests with mites seem worthy of record. About 50 newly emerged non-gravid females were placed in a small deep watchglass ($\frac{1}{2}$ in. diameter) which was inverted on the skin of the inner face of the forearm of the writer. The atmospheric temperature was 20° C. (68° F.), and the temperature under the clothing at the point of application was 32° C. (89.6° F.). The watchglass was held in position by a rubber band, and removed at the end of one hour. No lesions developed.

On another occasion 10 mites were applied in a similar fashion, just before going to bed. Three and a half hours later they were removed. Five hours later signs of lesions could be detected. In another four hours these were distinct, rosy red in colour, and with a small pustule at the centre. About 20 hours after exposure they were considerably swollen, each lesion having a central pustule as big as a pin's head. Some oedema of the surrounding area was present. They did not begin to

Fig. 6.—Camera-lucida drawing of a larva of the Grain Moth, *Sitotroga cerealella*, on which a number of female mites are feeding. They have fed for $1\frac{1}{2}$ days at 26° C., and show early stages of engorgement. The larva is entirely immobilised.

itch until 24 hours had elapsed. After a further 12 hours the oedema was much reduced and itching had ceased. It could still be renewed by rubbing 72 hours after the original exposure.

Webster (1910) gives figures of typical cases. The characteristic symptoms are well described by Goldberger and Schamberg (1909). They point out that the condition is at times mistaken for "hives," chickenpox, and scabies. In normal infestations malaise or systemic symptoms do not present themselves. In Australia it would appear that the agricultural worker endures the trouble where it occurs, as a normal hazard of his calling, and may not associate it with any living cause existing in the material he is handling. In view of its transient nature, a medical adviser is not consulted. This probably accounts for the fact that the condition has not hitherto been reported in Australia, so far as can be ascertained.

The literature contains a number of references to treatment. These consist, in general terms, of methods of allaying the irritation, and precautions to prevent secondary infection of lesions broken by scratching. Where infested material must be handled, a hot bath as soon as possible afterwards is recommended. The sprinkling of flowers of sulphur in working clothes has been used to repel the mites (*e.g.*, Thompson, 1925).

X. FARMING PRACTICE IN RELATION TO HAY, AND ITS INFLUENCE ON THE
PRESENCE OF *Pediculoides*.

In Australia wheat and oats are the most-used hay crops in the cereal belt. It is the standard practice to cut the crop some time after flowering. Immediately after flowering, the grain in the ears begins to fill out, the process occurring rapidly under Australian conditions. The sheaves are stooked and allowed to dry for some three weeks after cutting, and are then stacked. The resulting hay contains well-developed grain in the ears. There is a prejudice on the part of buyers of chaff in favour of a product in which developed grain is present. From the grower's point of view, an appreciably greater yield of hay is obtained by cutting towards maturity than at an earlier growth stage, *e.g.*, flowering.

It is, however, well known that cereals possess a higher nutritive value at flowering than at the dough stage, or at full maturity of the grain. Until that time the food materials in the plant are located principally in the leaves and developing ears. As the ear matures these materials become gradually concentrated

Fig. 7.—Appearance of a group of mites on the shrivelled remains of a grain moth larva. The arrow indicates the original long axis of the larva. (Camera-lucida drawing.)

in the grain, until ultimately the latter represents the chief feeding value of the plant, the straw consisting mainly of indigestible fibre. There are, however, several ways by which the original grain content of such material is reduced before it comes to be fed. In the stack the grain provides suitable food for the Grain Moth, *Sitotroga cerealella*, which reaches large numbers rapidly. It is very constantly present in such stacks, and may destroy a large part of the grain present in the ears. With late-cut hay it may greatly reduce the feeding value of the hay. A certain part of the grain is lost through falling out, while mice undoubtedly account for significant amounts.

As far as *Pediculoides ventricosus* is concerned, it has already been pointed out that, in hay stacks, it feeds chiefly upon the larvae of *Sitotroga*.

The advantages of early cutting (*i.e.*, at flowering time) may therefore be tabulated as follows:—

1. A material increase in the feeding value of the hay is obtained, although the actual yield is decreased. This decrease is largely compensated by the increase in nutritive value and digestibility obtained.

2. The Grain Moth is controlled.
3. The mite, *Pediculoides*, which feeds on this, is checked.
4. The possibility of "hay itch" is greatly reduced.

It may be added that such hay will offer less support for mice, often a source of serious damage where grain is present.

It is realised that it is often less convenient to cut hay crops at this time, and the weather is frequently less suitable for curing. Mr. H. C. Trumble, Agronomist at the Waite Institute, has suggested that an alternative method of conserving the earlier cut forage would be as stack-silage. Owing to the rapid development of grain after flowering (a week may be sufficient to allow appreciable development) it is difficult to avoid a certain amount of it in the stack. It is considered that in regions where "hay itch" is a problem, this harvesting practice should be aimed at. It is supported by a consideration of the relationships of the moth to the hay-crop, and the mite to the moth. Further, the curing process will not be much longer than for the later cut crop.

In conclusion, it is suggested that if a stack from a late-cut crop is to be made, at a farm with a previous history of "hay itch," it should be built on a new clean site each year, some distance from old sites, and that old or residual hay should not be used for flooring or thatching, owing to the risk of infecting the stack with mites that were over-wintering in this material.

XI. ACKNOWLEDGMENTS.

The writer has pleasure in acknowledging valuable help and assistance from a number of persons. Dr. J. Davidson has at all times given encouragement and information of the greatest value, and has read through the manuscript and made many valuable criticisms. Mr. H. C. Trumble, Agronomist, and Dr. J. G. Davies, Agrostologist, at the Waite Institute, gave much helpful advice and information on various aspects of Section X. Mr. H. Womersley, Entomologist at the S.A. Museum, has aided from his wide knowledge of the mites, and in regard to literature. Finally, thanks are tendered to Professor J. B. Cleland, Professor of Pathology in this University, for his interest and advice on the medical side of the problem.

XII. SUMMARY.

1. *Pediculoides ventricosus* Newport is recorded from South Australia.
2. Details of its biology and life-history are given.
3. Its rôle in "hay itch" is discussed.
4. Suggestions for its prevention in stacks are made.

APRICOT PRUNING AND MANURING AND FROST PREVENTION—CROP RECORDS.

[By J. B. HARRIS, Dip. Hort., Horticultural Instructor.]

APRICOT PRUNING.

An experiment to determine, if possible, the influence of "long" and "short" pruning of apricot trees on the prevalence of gummosis has now been in progress at Light's Pass for some years, the trees having been planted in July, 1928. For an account of the experiment up to July, 1933, see *Journal of Agriculture*, vol. 37, pp. 394-398. No significant occurrence of gummosis has so far been noted, but the comparative cropping of the trees under the two systems of pruning is worthy of note.

As stated in the above journal, the crop during the 1931-32 growing season was disastrously affected by frost, and in January, 1932, only a few fruits, the weight of which was not recorded, were picked, chiefly from the ends of leaders on the "long" pruned trees. In January, 1933, the crop from the long pruned trees was 311lbs. net, and the crop from the short pruned trees 105lbs. net. During the past season, i.e., January, 1934, the long pruned trees produced 31 cases of fruit, equal to 1,674lbs. net, or 14cwts. 3qrs. 22lbs. from the 10th to the 28th January. The short pruned trees produced 28 cases, equal to 1,512lbs., or 13cwt. 2 qrs. of fruit from the 16th to the 29th January. Although the crops from the differently pruned trees were not separately graded, it was apparent to the pickers and other observers that the average fruits from the short pruned trees were appreciably larger than those from the long pruned trees.

APRICOT MANURING.

Although the application of fertilisers to the apricot trees in the manuring test at Light's Pass (see *Journal of Agriculture*, vol. 37, p. 185) was carried out according to schedule, the crop was subsequently destroyed to such an extent by frost on the nights of October 25th and 26th that when the remaining fruit was picked it was found that the crop was so small, and the comparative cropping of the plots so erratic, that the owners of the orchard did not consider the crop worth recording. It is proposed, however, to carry on this test for further years, with some provision for frost prevention, this plot having been twice damaged by frost during the progress of this experiment.

FROST PREVENTION BY ORCHARD HEATING AT LIGHT'S PASS.

The comparison of crops harvested from the heated and unheated or "check" plots in this test bears out the efficacy of orchard heating, as illustrated in the *Journal of Agriculture*, vol. 37, pp. 649-663. The crop harvested from the heated area—1 acre, planted with 70 trees—between January 3rd and January 23rd, 1934, was 88½ cases, approximately two-thirds of the fruit ripening from the 9th to 17th January. The crop from the unheated or "check" plot, consisting of 60 trees, harvested between January 3rd and January 17th, was 28½ cases, the bulk of which ripened between the 9th and 17th January. A most important point for consideration in connection with this test is the fact that 75 per cent. of the fruit from the unheated plot, i.e., 21.3 cases, was harvested from the 14 trees in the two rows adjoining the heated plot. These latter trees showed signs, immediately after the frost, of having benefited to some extent from heat radiated from the heated plot. It should also be borne in mind that, as explained in the above journal, both plots suffered alike from frost on the night of October 24th or early morning of October 25th, when, owing to an accident, no heating was carried out. Further reference to these figures in their relation to costs of orchard heating will be published in a subsequent issue.

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

DAIRY PRODUCERS' CONFERENCE.

The Third Annual Conference of Branches associated with the dairying industry was held at Milang on Wednesday, May 9th. Representatives were present from the Adelaide, Hartley, Langhorne's Creek, Finniss, Lyndoch, Strathalbyn, Jervois, McLaren Flat, Scott's Bottom, Belvidere, Cherry Gardens, Murray Bridge, Kangarilla, and Milang Branches.

Mr. P. J. Bailly (Member Advisory Board of Agriculture), Prof. A. J. Perkins (Director of Agriculture), Messrs. W. J. Spafford (Deputy Director), H. B. Barlow (Chief Dairy Instructor), and H. J. Apps (Senior Dairy Instructor), H. C. Pritchard (General Secretary) and F. C. Richards (Assistant Secretary, Agricultural Bureau) were present on behalf of the Department.

The opening address was delivered by Mr. Bailly.

PAPERS AND RESOLUTIONS.

The following papers provided excellent discussions:—"Dehorning," J. Y. Hudd (Adelaide); "Management of the Dairy Herd," A. Kelly (Milang); "Pasture Development," E. L. Goode (Narrung); "Care of Cream and Butter," J. M. Yelland (Milang).

Mr. Bailly presented Life Membership Certificates of the Agricultural Bureau to Messrs. F. Hassam and L. Mann, of the Milang Branch.

Conference carried the following resolutions:—"That this Conference request the Government to pass legislation to compel the dehorning of all bulls 2 years of age and

over used for dairying purposes." "That the 1935 Conference be held at Mount Barker," "That in view of the fact that 79 per cent. of the milk produced last season in South Australia was manufactured into butter, and during that period (1932-33) 150,000cwts. of butter were made in the factories and 45,000cwts. on the farms, and bearing in mind the importance of the butter industry to the State, this Conference is of the opinion that the utmost endeavour should be made to place the industry on a sound footing." "That this Conference does not agree with the Royal Commission's recommendation that the practice of payment for cream on a butterfat basis should continue, and is of opinion that payment should be made on the basis of commercial butter." "That this Conference is well aware of the widespread opinion among farmers that what has come to be known as 'manufacturing costs' in the butter industry are considerably higher than they should be." "That in order that the cream suppliers' interests may be the better served this Conference asks that immediate legislation be passed to give effect to recommendations 22, 23, 24, 25, 26, 27, and 29 of the report of the Royal Commission on Dairy Industry Prices, and that in the case of recommendation 26, representatives of the producers be associated with those of the Government and manufacturers." "This Conference recommends that the present expensive method of collecting cream for transport to the factories be abolished and that there should be substituted for it, possibly by legislation, a more economical method."

The evening session was occupied with an address by Mr. Barlow, "Pigs for the Overseas Market."

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on April 24th, there being present Messrs. A. J. Cooke (Chairman), R. H. Martin (Vice-Chairman), A. M. Dawkins, F. Coleman, P. J. Bailly, A. L. McEwin, A. J. A. Koch, Professor A. J. Perkins, Dr. A. E. V. Richardson, and H. C. Pritchard (Secretary). Apologies were received from Messrs. J. B. Murdoch and J. W. Sandford.

New Member.—The Chairman welcomed Mr. A. J. A. Koch as a new member of the Board.

Ridley Memorial Trust.—Mr. A. M. Dawkins was re-elected as the representative of the Board on the Ridley Memorial Trust.

Murray Lands East Conference.—The Board granted approval to the application of the Caliph Branch to hold the 1934 Conference of Murray Lands East Branches of the Bureau at Caliph.

New Branch.—Approval was given to the formation of a Women's Branch at Snowtown, with the following ladies as foundation members:—Mesdames W. Pellew, A. E. Michael, W. Stanton, A. and K. Andrews, A. Davidson, W. McDonald, J. Hancock, P. Wheaton, G. Freebairn, C. Lovelock, and Miss E. Kreig.

New Members.—The following names were added to the rolls of existing Branches:—Mangalo Women's—Mrs. O. Guy, Mrs. J. Hissey; Upper Wakefield—Cyril Webb, Arnold Smith, P. Ryan, John Ryan, M. Cleary; Booborowie—W. J. Shattock, F. Shattock, S. Shattock, Harry Baynes; Sutherlands—O. Jencke; Mundalla Women's—Miss M. Fisher, Miss Una Fisher; Gladstone—C. H. Lines, Roy Lines; Scott's Bottom—G. R. Langford; Beetaloo Valley—C. Curtin; Nantawarra—A. Bryant, F. Bryant, P. G. Palfrey.

The Board dealt with a number of items in Committee.

DAIRY AND FARM PRODUCE MARKETS.

MESSRS. A. W. SANDFORD & CO., LIM.

BUTTER.—The cold dry weather which was experienced last month caused a further shrinkage in supplies of dairy produce, and the minimum of production has now been reached. In one or two of the more favored parts of the State a slight increase in cream supplies was noticeable, but, in the aggregate, production is still almost stationary. During the month various conferences were held in this and other States to endeavor to arrive at a plan for stabilising the industry and in the eastern States a scheme has been arranged for this object. In South Australia it is proposed to arrange a State plan which, it is hoped, will function satisfactorily. Rates firmed at the end of the month and present values are:—Choicest creamery fresh butter in bulk, 1s. 3½d. (These prices are subject to stabilisation levies.) Store and collectors lots, 6d. to 7d. per pound.

CHEESE.—The South-Eastern factories marketed quantities of all sizes throughout the month. Local and Westralian trade was again well maintained and ready clearances effected. Production is now down to a low level, but, as rains were received in the Gambier district, it is expected that a gradual improvement will take place from this out. The present rates are as follows:—Large and medium, 7½d. to 8½d. per pound; loaf, 8½d. to 8¾d.; semi-matured and matured, 8½d. to 9½d. per pound.

EGGS.—As usual during the cold weather the supplies of eggs have fallen back and production at the present time is about at minimum. However, there is more than sufficient for local needs, and some shipments have gone forward each week to Sydney. Rates moved forward during the month and at present are as follows:—Ordinary country eggs, hen or duck, 9d. per dozen; selected fresh eggs, 1½ozs. and over, 1s. to 1s. ½d. per dozen.

BACON.—Although the turnover in bacon has shown steady improvement, which is usual at this time of the year, the demand for hams has slackened. However, there was little demand during the month for farm cured bacon as storekeepers generally preferred to handle the factory cured bacon of the established brands. Rates have continued on an even keel throughout and are as follows:—Best quality sides, 9½d. to 9¾d.; middles, 10½d. to 11d.; rolls, 8d. to 8½d.; hams, 11½d. to 1s.; cooked, 1s. 2d. to 1s. 2½d.; lard prints, 5½d. per pound.

ALMONDS.—It is generally expected that the quantity of almonds gathered this year will be considerably less than last season. The consignments received in the open markets during the month were only limited and there was no difficulty in quitting them from day to day. Present values are:—Softshells and Brandis, 7½d. to 8d.; hardshells, 4½d. to 5d.; kernels, 1s. 9d. to 1s. 10d.

HONEY.—This commodity also is shorter in supply this season than last, and it is expected that the quantity gathered will not be more than 30 per cent. or 40 per cent. of last season's take. However, there was a large carry-over from the previous season, so that no difficulty is being experienced in meeting the demand from week to week. Rates are as under:—Prime quality clear extracted in liquid condition, 3½d. to 4d. per pound. Special quality odd tins, 4½d. per pound; lower grades, 1½d. to 2½d. per pound.

BEEFWAX.—Stocks are light and prices moved forward to 1s. 4d. to 1s. 4½d. per pound.

POTATOES.—New season's, 9s. per cwt.

ONIONS.—Brown Spanish, 6s. per cwt.

LIVE POULTRY.—As usual, after the Easter markets supplies of poultry were considerably less, but, during the past few weeks, there has been a much larger quantity of birds sent forward. As most poulterers have now almost exhausted their supplies held in cold store, they are operating freely from sale to sale and rates are, therefore, well maintained. During recent markets there has been a shortage of prime quality heavyweight turkeys, and values for these have been high. We advise consigning. Crates loaned on application. The prices at present ruling are as follows:—Prime roosters, 3s. 2d. to 4s. 3d.; nice conditioned cockerels, 2s. 7d. to 3s. 1d.; fair conditioned cockerels, 1s. 9d. to 2s. 6d.; chickens lower; heavyweight hens, 2s. 3d. to 3s. 3d.; medium hens, 1s. 9d. to 2s. 2d.; light hens, 1s. 4d. to 1s. 7d.; couple of pens of weedy sorts lower; geese, 2s. to 3s.; goslings, lower; prime young Muscovy drakes, 3s. to 4s.; young Muscovy ducks, 2s. to 2s. 9d.; ordinary ducks, 1s. 3d. to 2s.; ducklings, lower; turkeys, good to prime condition, 9d. to 1s. per pound live weight; turkeys, fair condition, 7d. to 8d. per pound live weight; turkeys, poor and crooked breasted, lower; geese, 3½d. to 4½d. each.

RAINFALL TABLE.

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall at the subjoined stations for the month of April, 1934, also the average precipitation for April, and the average annual rainfall.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[Branch Secretaries are reminded that the following are exempt from payment of the Annual Bureau subscription:—Life members, Branch Secretaries, members appointed before August 1st, 1930, and new members who reside in the same house as (a) a life member, (b) Secretary, or (c) another member who already subscribes.

The subscription for all other members is 2s. 6d., commencing from August 1st in each year, provided that—subject to the above exemptions—nominations forwarded during the months of January to June must be accompanied by a payment of 1s. 6d. each nomination for that period.]

MEN'S BRANCHES. SOUTH-EASTERN DISTRICT. POISONING TREES.

[Paper read by Mr. F. J. R. Dinning at the April meeting of the Mundulla Branch.]

The formula recommended is as follows:—1lb. of arsenic, 1lb. of washing soda, 1gall. of water; boil on a slow fire until the liquid is quite clear and free from white particles; give an occasional stir, care being taken not to inhale the fumes. The mixture can be boiled in kerosene buckets by putting in 4lbs. each of arsenic and washing soda and adding 3galls. of water; then make up to 4galls. by adding enough hot water to fill the bucket just before taking it off the fire.

It is very difficult to prevent the mixture from boiling over in the early stages. To guard against this, a slow fire is necessary. If the soda is crushed very finely, dissolved in boiling water and then poured slowly on the arsenic and stirred a little before hanging over the fire, there will be less danger of boiling over. A slow fire, out in the open air, should always be used to lessen the danger of inhaling the fumes, which are very poisonous. Because of the poisonous nature of the fumes, the liquid should not be used until quite cold.

METHOD OF APPLYING.

Trees which are large enough to frill ring; a frill should be cut through the bark just into the sap-wood. About one chop deep around the tree is all that is required. Each chop with the axe must link up to complete the ring, but the chip should not be taken out, thus leaving an open frill at the top, so the liquid can be poured in easily.

The ring should be near the ground—the nearer the ground the less likely the shoots are to grow. Ring about 6in. from the ground on all small trees, and a little higher on old timber. Trees that are too small to ring can be cut down level with the ground and sufficient liquid poured on the stump to wet the top of the stump. This method will kill mallee also.

To apply the liquid, a can that will hold 3 pints is necessary. It should be shaped like a watering can without the sprinkler, and have a nozzle opening that will admit a piece of No. 10 wire. The can should be fitted with a strainer made of fine wire screen, otherwise pieces of bark, sticks, &c., block the nozzle of the can and prevent free running.

The quantity of liquid required is just sufficient to wet the inside of the ring of the tree, that is, the stream from the No. 10 nozzle, as you walk around the tree, will do the job, but it must connect, with no patches missed.

THE BEST TIME TO POISON.

The best time of the year to poison is when the sap is down; during May, June, July, and August, June and July for preference. Poisoning during summer does not kill the stump. The trees usually show signs of withering from 5 days onwards, and usually die within a month.

The trees should be poisoned as soon as rung so that the liquid mixes with the sap. Trees rung an hour before poisoning do not take the poison readily. A good method where men are available is for two to ring and one poison.

When only a small quantity of liquid is required, caustic soda can be used in place of washing soda. This does away with the necessity for the cumbersome job of boiling. 3lbs. of caustic will dissolve 4lbs. of arsenic without boiling. However, caustic soda is too costly when large quantities are needed.

CARE NECESSARY WHEN HANDLING.

Care should always be taken not to get the liquid in cuts or sores, and if clothes are saturated with the mixture it will take the skin off the body. Do not get it in foot-wear or it will cause serious burns.

UPPER NORTH DISTRICT.

(PETERBOROUGH AND NORTHWARD.)

WILMINGTON (Average annual rainfall, 17.43in.).

April 10th.—Attendance, 15.

DEBATE.—“Merits of Jersey v. Shorthorn Cattle as Sidelines on the Farm.” For Jerseys—Messrs. M. H. Modystach, S. C. Genders, and O. A. Haase. For Shorthorn—Messrs. H. Duhring, G. Fraser, and J. L. Moroney. Mr. E. L. Orchard acted as adjudicator. Jersey, 286 points; Shorthorn, 255 points.

QUESTION BOX.—*Storing Cocky Chaff.*—If it is proposed to store the chaff for any length of time, the best method is to provide a proper shed for the purpose. Failing that, the best way is to erect uprights about 5ft. apart, the length and height depending on the quantity of chaff. Wire netting is then fastened to the uprights. It is a good plan to lay flag stones at the bottom to prevent moisture soaking into the chaff and making it mouldy. A square enclosure is the best, because the wagon can be backed into it and each load built up, trampling it down well occasionally. Build chaff 2ft. above the netting before starting the gable roof, otherwise the setting down spoils the netting and the straw covering will dip to the inside, leading the water into the stack.

Cure for Sore Shoulders.—Cut a hole in the collar or remove the stuffing in the collar at the point, sewing a ring around to keep the place empty. After the sore has healed the stuffing may be replaced. It is advisable to bathe the affected part with white lotion every four or five hours. After the wound is clean one of the gall ointments advertised by veterinary firms may be applied. (Secretary, C. Cole.)

(PETERBOROUGH AND NORTHWARD.)

BQOBOROWIE.

April 5th.—Attendance, 15.

HARVEST REPORT.—Mr. E. A. Bristowe presented the following:—“Dan and Free Gallipoli thin and very short, but yielding a return beyond expectation—22bush. Federation and Bena, 8 bags. Merriden sown in the hills, which members of the

Branch inspected early in November, then looked very disappointing. A nice rain near the end of the month worked wonders on this crop, and it returned a yield of 10 bags. Mr. Bristowe then gave a short discourse on the comparison of the rainfall and the wheat prices over a lengthy period of years, finishing with a review of the growth of the world's population, which increased a little faster right through history than did the produce of the agriculturist until about 1928, when the increase in the growth of population suddenly ceased and the produce of the agriculturist increased and brought about a surplus that is glutting the world's markets to-day. (Secretary, A. Mayfield.)

BLYTH (Average annual rainfall, 16.80in.).

March 2nd.—Attendance, 16.

SEED WHEAT COMPETITION.—Mr. W. Eime read the following paper:—"The Seed Wheat Competition which has been so successfully conducted during past years has resulted in raising the standard and quality of crops in this district, and it would be a retrograde step if it were abandoned. I suggest that we have a Competition of seed wheat as used by members. Samples to be taken from two varieties of 90bush. each, and the wheat to be ready graded and pickled. For the scale of points I suggest the following:—

	Points.
Weight per bushel	15
Plumpness and evenness	15
Freedom from weeds, seed, smut, barley, &c.	25
Trueness to type and freedom from visible admixture	18
Freedom from injury in harvesting	17
Freedom from dirt, chaff, straw, &c.	10

100

Freedom from barley, weeds, and seeds is more important than weight per bushel. The entrant to sign an assurance that nothing more than the usual cleaning for the drill had been done with the wheat. At the Royal Show 15 points is allowed in the milling class for weight per bushel. For seed wheat, weight per bushel does not count. Another class.—One variety of 15bush., also pickled, is recommended:—

	Points.
Weight per bushel	20
Plumpness and evenness	15
Freedom from weeds, seeds, smut, barley, &c.	25
Trueness to type and freedom from visible admixture	15
Freedom from injury in harvesting	15
Freedom from dirt, chaff, straw, &c.	10

100

In this class the method of cleaning could be left in the hands of the entrant. The prizes need not involve a large sum of money. The quantity suggested should suit most farmers, for they mostly sow 90 or 100 acres of two favorite wheats, then the man that cannot compete in the big lots has the small amount to put up. He can afford to clean his better. There would be nothing to prevent a farmer putting the same wheat in both Competitions." It was resolved to take samples of pickled or unpickled grain from a stack of not less than 60bush., and that the following scale of points be used for judging: Plumpness and evenness of grains, 25; freedom from weed seeds, 25; freedom from visible admixture, 15; freedom from injury in harvesting, 25; freedom from dirt, chaff, &c., 10; total, 100 points. (Secretary, R. Eime.)

March 23rd.—Attendance, 14.

DRY PICKLING WHEAT.—In the course of a paper under the heading, "What quantity of dry pickle is necessary as a certain preventive against bunt?" Mr. P. Fiegert said:—"There is no exact quantity of dry pickle that can be claimed as a sure preventive against bunt, because districts are so different and the methods carried out in some parts of this State would be quite unsuitable in others." Members in discussing the paper were of the opinion that dry pickle was far superior to wet pickle with wheat, but not with barley. For wheat 1oz. to 1½ozs. per bushel of copper carbonate was considered sufficient.

DESTRUCTION OF FOXES.—Paper read by Mr. J. Pratt:—"When the skins are of little or no value I suggest poisoning with strychnine, using for baits fresh beef or mutton; a ball of caul fat is also very good. Perhaps the best baits are pigeons or sparrows—foxes take them readily, and a dog is not likely to pick them up. Use a drag and drop the baits right on the trail—around dams or water troughs is an ideal place in summer. When ewes are lambing and a lamb partly eaten by foxes is

found, poison it, being careful not to touch it with your hands. When ewes are lambing shift them to another paddock, and drop a few baits at the gate through which the flock passes. A stale sheep's head also makes an effective drag." In the discussion that followed members referred to the various methods of killing foxes. It was reported that one outstanding and simple method of fumigation was to place a burning bag or bundle of straw down the burrow. The fox would attempt to get out of the burrow at the first smell of smoke, and would be killed endeavoring to fight the fumes at the opening of the burrow. Each time that had been tried the fox had been found dead about 3ft. from the mouth of the burrow. (Secretary, R. Eime.)

BLYTH SEED WHEAT COMPETITION.

[Judged by Messrs. F. Coleman and W. C. Johnston, R.D.A.]

Class v. Best Collection of Two Varieties.—Messrs. T. Williams and H. E. Zweck tied for first place, each gaining 186.5 points. Both names of the successful exhibitors will be inscribed on the trophy presented by Messrs. H. J. Penno & Co., Ltd. Third prize was won by Mr. H. W. Eime, gaining 185.75 points.

Results.—T. Williams—Rance, 95.75; Ford, 90.75; total, 186.5. H. E. Zweck—Rance, 93.5; Sword, 93.0; total, 186.5. H. W. Eime—Rance, 96.25; Ford, 89.5; total, 185.75. A. L. McEwen—Rance, 94.5; King's Early, 90.25; total, 184.75. F. W. Zweck—Rance, 90.75; Nabawa, 92.5; total, 183.25. H. A. Zweck—Ford, 88.0; Sword, 93.75; total, 181.75. L. C. and R. H. Mugge—Currawa, 92.0; Ford, 82.75; total, 174.75. L. C. and R. H. Mugge—Sword, 87.5; Currawa, 92.0; total, 179.5. W. O. Eime—Rance, 83.75; Sword, 83.5; total, 167.25. Mr. H. W. Eime's Rance, with 96.5 points, gained the champion trophy presented by E. H. Lanyon, Esq. (Secretary, R. Eime.)

LOWER-NORTH DISTRICT.

(ADELAIDE TO FARRELL'S FLAT.)

BLACK SPRINGS.

February 27th.—Attendance, 14.

SHEEP ON SMALL HOLDINGS.—Mr. J. Heinrich read the following paper:—"With the continued low prices for wheat and dairy produce, the small landholder will more or less change over from wheat farming to wool growing and fat lamb raising, this is not an easy matter in a time of depression. In the first place, the farm must be sheep-proof fenced and each paddock must have an ample supply of water. The farmer will ask himself the question, What shall I do with my stock and plant? There is no need to sell out, but instead of cultivating and growing only wheat he should revert, to some extent, to barley and oats. These cereals can be fed to ewes, who in return would profitably return a high class lamb and a good fleece. At present prices a good ewe rearing a lamb would net about 30s. a year. In some instances the farmer would find it difficult to finance the purchase of a flock of good ewes, but he may obtain assistance to do this, for otherwise I am convinced it is a good proposition. Sheep are very interesting, and the farmer will soon gain a fair knowledge, especially if he goes to a successful breeder in his district who would be only too pleased to give him timely advice. Better still, he should join an Agricultural Bureau in his district. Another factor that must not be lost sight of is that a high class ewe be kept. For preference, a Merino ewe producing a heavy fleece of good quality could be mated to Dorsets or other English breeds for export lamb raising. At present the Merino would be quite sound if good flock rams are used from a reputable breeder. By growing cereals and feeding to sheep the revenue from the farm could be considerably increased." (Secretary, K. Dunn.)

FRAYVILLE.

April 5th.—Attendance, 14.

POULTRY AS A SIDELINE.—Paper read by Mr. L. Eichler:—"Some hold the mistaken idea that poultry can exist and pay under the most adverse conditions, and if they do not, then it is the fault of the fowls. Every competent authority agrees that failure with poultry is the fault of the operator. The good laying strains are White Leghorn and Black Minorcas, and for table birds and fair layers the Black Orpington, Rhode Island Red, Wyandotte, and Plymouth Rock. A flock of 100 good layers will return 20 to 30 per cent. more eggs in a year than will an equal number of ordinary stock. They cost no more to feed. The fowls need a shed for roosting, not draughty but well ventilated, to keep the birds as healthy as possible. Disease once started will very quickly spread through the flock. Keep the shed as clean as possible, and spray with a solution of kerosene or a mixture of old motor crankcase oil and kerosene. This will kill poultry tick and red mite. If this is done fortnightly to the perches there will be no sign of scaly legs. Points to notice in examining a hen which has laid well:—Vent bluish-coloured, eyelids thin and edges white, eyes keen and sparkling, plumage worn, soiled, and close feathered. A poor layer:—Vent flesh-coloured, eyelids thick, yellow tinted, if moulting has not occurred; coarse-headed hens are invariably poor layers, the head should be acute, the face almond-shaped, and back of head long. Poor layers have a thick dry skin underlaid with fat; the good layer, the skin should be soft, thin, loose, and silky. To clean up the fowls, handle each bird, examine the mouth, see that it is clean from dangerous growths, &c. If affected, dust the part with powdered bluestone. Look for body parasites and dust well with insect powder. Have a mixture of salad oil 4 parts and kerosene 1 part; clean the shanks with this, and apply a very little to the face, comb, and wattles, especially behind ear or ear lobes. This helps to keep off chickenpox. **Broodiness.**—Where egg production is the main objective, broodiness among the layers is a nuisance and entails much work. Put a leg band on such hens and place in a coop until the fever is over. If she is a good layer return her to the flock; if not, send her to market. The less broody hens the better. The quicker they are cured the better. The broody instinct may last for five or six weeks, and sometimes longer. Some heavy breeds are more inclined to brood than light breeds. The purer the flock the less broodiness." (Secretary, H. Ramm.)

LIGHT'S PASS.

February 16th.—Attendance, 23.

Members exhibited home-made gadgets and labor-saving devices for use on the farm. Several interesting and useful models of the different home-made tools and implements were shown, and their uses explained. Mr. Stewart, of the A.D.F.A. addressed the meeting, giving several useful and novel ideas of trapping sparrows and starlings, which at present are doing a great deal of harm.

On February 28th members made a trip of inspection to the Hackney Experimental Vineyard, where they were met and conveyed through the garden by Mr. G. Quinn. They afterwards proceeded to Mr. N. Wick's nursery, where a pleasant and instructive evening was spent. (Secretary, C. Verrall.)

NANTAWARRA (Average annual rainfall, 15in.).

March 10th.—Attendance, 10.

FAT LAMBS.—Mr. E. G. Herbert read an article from the *Journal of Agriculture*, "The Production of Fat Lambs for Local and Export Trade." Discussion: Mr. E. V. Hamdorf favored the Dorset Horn crossed with a Merino ewe for lambs. He also thought the Border Leicester-Merino a good cross. Yarding the flock every second night was advisable. Mr. K. Young thought the Dorset Horn-Merino the best cross for the farmer to breed lambs. Mr. A. Herbert said it had been proved that the crossbred produced the best lamb, but the pure-bred Merino was the most satisfactory on a mixed farm, as the ewes could be kept for breeding when necessary, as well as being less troublesome. The small difference in the price of lambs would be practically made up by the heavier and better wool clip. (Secretary, S. Herbert.)

OWEN.—February 12th.

HARVEST REPORT.—Mr. J. Harkness, in giving a report of the 1933-4 harvest, first reviewed the rainfall and climatic conditions of the past year, and continued by saying that by the beginning of October everything pointed to a good return, with plenty of hay. We thought that the dry winter had made the roots of the plants go deep in search of moisture, and with a few frosts the wheat plant should be tough enough to withstand the usual hot winds. The conditions from mid-September to mid-October were very dry and followed by hot winds, one or two days being very severe. It appeared, before the hot winds, that the harvest would be later than usual, but

the crops seemed to mature as much in the fortnight as they should have taken a month to do. Some patches a little on the rank side turned from green to white, and later broke down, and consequently yielded nothing. After this disastrous period of heat and wind, the weather settled down to ideal ripening conditions, but the effects of hot winds were apparent in all varieties. Weeds were rather prominent in most crops, particularly wild mustard, which seems to thrive when crops receive a check. A comparatively new weed, the rat-tailed poppy, was rather prominent in one paddock, and, if not watched carefully, will spread rapidly. Our most dreaded disease, red rust, was conspicuous by its absence, after having been with us for the two previous years. Take-all was a little more prevalent than usual, probably the cause of this being the lack of winter rains to solidify the soil, which was left too open. There was a sprinkling of hull smut throughout some varieties, no doubt for the want of more care at pickling time. Flag-smut was present, but in a lesser degree than usual, owing, no doubt, to so much Nabawa being grown. One of the most disappointing features of the harvest was the pinched sample of light-weighting wheat. In some cases we have never reaped poorer wheat, and never such poor grain in the absence of red rust. The chief offender in this regard was the variety Nabawa, more or less our standard wheat, which has been a consistently good yielder for many years. Throughout this district it was almost a consistent failure, but I think it will do well in future, all the same. It yielded with us from 12bush. to 20bush. per acre. Sword was the outstanding variety, yielding 34bush., the sample being fair and weighing light. The best grain came from Waratah, which yielded about 24bush. Ford grew a lot of straw as usual, and returned 24bush.; also Nawab, while not growing as much straw as Ford, yielded about the same. The farm average was 22bush. Two patches of English barley each returned 8 bags to the acre, one lot being fair grain and the other poor. With regard to oats, three varieties—Guyra, Mortgage Lifter, and Mulga—were grown. Guyra performed best, yielding approximately 30bush. of plump oats, standing up to winds fairly well, and not shedding the grain as much as the other two varieties. Mortgage Lifter returned about 27bush., but the grain was very thin, and the crop went squashy in places. Mulga oats are somewhat new to this district; they are an early market variety, fairly good hay, and the grain is almost white. The variety yielded about 20bush., and although caught by hot winds, filled a fairly plump grain.” Other members contributed information regarding their crops. (Secretary, M. Freebairn.)

ROSEWORTHY (Average annual rainfall, 17.46in.).

March 3rd.—Attendance, 26.

SHEEP VERSUS WHEAT.—Paper presented by Mr. R. Tremlett:—“This subject is one of especial interest to local farmers situated in this favorable district. For purposes of comparison it is proposed to deal with:—(1) Wheat as the chief cereal crop and entirely as the first consideration, but the growing of malting barley to be allied with it—this being the most favored rotation in this district. (2) Sheep, firstly for the production of fat lambs, and secondly for wool. As a practical demonstration of the relative values of wheat and sheep, I intend to take an average farm of 600 acres. The chief interest in this subject must lie in the possibilities of both wheat and sheep at the present moment, under the existing conditions, and not purely and simply as an alternative undertaking by a farmer just commencing one or the other. In taking an average farm for this comparison I have assumed it to be fenced with a six-wire fence, together with the usual improvements.

Wheat (600-acre farm).—200 acres of wheat each year; 200 acres of barley grown on the wheat stubbles; 200 acres of bare fallow. A study of the wheat yields of this district shows that over a period of years a 9-bag average will be maintained, and a 7-bag crop of barley on the wheat stubbles. Thirty acres of the wheat crop must be cut for hay for the feeding of the farm team of 12 horses—an adequate number for the efficient working of the above farm—leaving 170 acres under wheat. Gross income at last harvest prices for grain:—

	<i>Income.</i>	£	s.	d.
170 acres of wheat at 9 bags per acre = 1,530 bags at 2s. 3d. per bushel .		516	7	6
200 acre of barley at 7 bags per acre = 1,400 bags at 2s. per bushel . . .		420	0	0
		<hr/> £936 7 6		

equals gross income except for the deduction of horse feed.

The expenditure side of the ledger must now be examined. The land itself, together with usual improvements, must be valued at ruling rates—approximately £12 per acre. This item is really almost immaterial, as it will be an equal deduction on both wheat and sheep.

<i>Expenditure.</i>		£	s.	d.
Purchase price of land (£7,200) at ruling rates of interest (5 per cent.)		360	0	0
Superphosphate		76	0	0
Seed wheat		40	0	0
Seed barley		30	0	0
Cornsacks		87	0	0
Bindor twine		4	0	0
Sewing twine		2	0	0
Pickles		2	0	0
Shares, &c.		3	0	0
Shoeing, &c.		3	0	0
Depreciation of farm plant valued at £700 at rate of 10 per cent. per annum		70	0	0
Depreciation of farm team valued at £360 (being £30 per head) at rate of 10 per cent. per annum		36	0	0
Interest at rate of 5 per cent. per annum on capital outlay of machinery and horses (£1,1060)		51	0	0
Wages (1 man for 12 weeks' harvest); wages also for the rest of year (40 weeks)		116	0	0
Total expenditure		£880	0	0
		£	s.	d.
Total gross profit		936	7	6
Less total expenditure		880	0	0

Leaving a net profit of £56 7 6

This amount is not actually the net profit for no provision has been made for maintenance of farm improvements and buildings, but for purposes of this discussion the above figures are accurate enough.

Rates and taxes have been entirely omitted as they are an equal deduction on either side.

SHEEP GROWING.

There is a general tendency to regard sheep farming as being of a much easier nature than wheatgrowing. On many different grounds this idea may be combated. In wheatgrowing there is a regular routine to follow which has differed only slightly over the last 20 years. Grass farming is a highly scientific study in so far as the cumulative effect of top-dressing, and the pasture must be given every consideration together with the improved fertility of the soil so that it can be readily seen that for comparison purposes with wheat it is not the profits which are made the first year but over a period of years which must be considered. Local farmers are very apt to regard sheep as a sideline and pastures as a secondary consideration. This view is quite natural, situated as we are in country which up to the present time has been almost entirely devoted to wheat. The actual figures relating to Australia's primary production are very interesting as follows:—65 per cent. of Australia's products grown on grass; 35 per cent. wheat and cereal growing. The vital point in this discussion lies in the one question, 'How many sheep per acre can be carried'? This question is one which can be studied from several different angles:—(1) To rely on natural pasture. (2) Top dress the virgin pasture with superphosphate. (3) Put down a sown pasture. I propose to adopt the top dressing of natural pastures. Experiments conducted at Kybybolite Experimental Farm give some astonishing figures in this respect:—Virgin pasture, 0.92 sheep per acre; 50lbs. superphosphate, 2.88 sheep per acre; 90lbs. superphosphate, 3.25 sheep per acre; 180lbs. superphosphate, 3.45 sheep per acre. Studying these figures it will be seen that the most economical dressing of superphosphate would appear to be at the rate of 90lbs. per acre, and I shall adopt this amount as being the most suitable for this district. Kybybolite figures show that this dressing can be applied at a cost of 5s. 6d. per acre. For a similar application in this district we shall be forced to rate it a little higher as the work would have to be let by tender as no power would be available. The actual costs of the super is approximately 3s. 9d. per acre, which, together with the cost of application, equals 5s. 9d. per acre.

Most of the fields in this district show definite traces of clover in the pasture, and only require dressings of super to encourage their growth. At Roseworthy College it was readily seen on inspection days that nowhere else in the district was there such a magnificent crop of clovers. This is undoubtedly due to the heavy dressings of superphosphate which have been applied to previous wheat crops leaving a fairly large residue of super available for the pasture.

On our own farm a paddock of 50 acres was sown to wheat, 25 acres of it was cropped to barley the following year, while the other 25 acres was fallowed. On the land which was fallowed there was no trace of clover, while that which had barley on it had a prolific crop of clover in the straw. The whole paddock was again sown

to barley, and prior to fallowing it the following year the land which had had three successive dressings of superphosphate had an enormous lift of clover intermingled with King Island melilot, while that which had only one dressing of super was quite bare. This clearly demonstrates that the seed is always present in the soils, and only awaits the dressings of super to promote their growth.

Taking an identical farm with the one used for wheatgrowing, fenced in the ordinary manner—namely, 80-acre paddocks—I intend to further subdivide it by two easily removable fences. By so doing the stock-carrying capacity can be materially increased. These fences can be easily constructed of cyclone and corkscrew droppers, and can be used to subdivide each 80-acre paddock in turn. I suggest dividing the whole flock into two smaller flocks, and grazing each 40-acre paddock once in eight weeks so that in this way the feed which has been eaten back short has time to recover and make fresh headway.

How many sheep can be carried? By top dressing it with 93lbs. of super I consider it will carry two sheep per acre, provided some provision is made during summer for hand-feeding. As it is intended to carry breeding ewes together with lambs up to the marketing stage it can be readily seen that it would be an impossibility to carry as many ewes as wethers, so that approximately 1,000 ewes would equal 1,200 wethers. Therefore there would be a basic flock of 1,000 ewes together with lambs to be carried.

There are many alternative methods of hand-feeding the sheep during summer such as ensilage, nuts, oats, barley, hay-chaff, &c. These methods are entirely optional. There should be an adequate supply of dry feed and roughage available throughout the summer, and this can be considerably augmented by a judicious withdrawal of the flocks from certain paddocks toward the end of the growing period. Nuts can be fed to advantage over a period of five months—from the beginning of the year until the end of May—thus giving the pastures time during May to make some little headway. The nuts can be fed judiciously at a cost of 2d. per sheep per week, so that 1,000 sheep will cost £8 6s. 8d. per week, making the total for handfeeding over a five-months period £175. These can be fed more equitably on a prepared piece of ground than in the feeders, for in this way each sheep will get its share.

With due care it should be possible to obtain a 90 per cent. lambing actually marketed. In taking the wool prices of 16d. this figure must remain more or less conjecture, for no doubt the quality of the wool would be materially increased compared to the quality now existing; 1,000 2-year-old ewes bought at existing prices (approximately £1 per head) equals £1,000. Using one British bred ram to each 50 ewes it would be necessary to purchase 20 rams at £3 3s. per ram, which equals £63. These figures may be considered a little high, but the maxim must be:—'Quality first,' thus resulting in higher figures for the products. I am using Merino ewes for the basic flock mated to a British breed of ram combining high values for wool and suitable lambs.

SHEEP.

<i>Revenue.</i>	£	s.	d.
900 lambs (33lbs. per lamb at 5d. per lb.; skin, 2s. 6d.) at 16s. 6d. per lamb	742	0	0
1,000 sheep cutting a fleece of 11lbs. per sheep = 11,000lbs. of wool at 16d. per lb.	733	0	0

Gross profits realised	£1,475	0	0
----------------------------------	--------	---	---

Expenditure.

	£	s.	d.
Interest on capital outlay for purchase of farm	360	0	0
Interest on capital outlay on purchase of ewes and rams	53	0	0
Cost of application of 93lbs. of super at 5s. 9d.	172	0	0
Costs of hand-feeding	175	0	0

— water	5	0	0

Total expenditure	£1,064	0	0
-----------------------------	--------	---	---

Leaving a net profit of £411.

Sheep growing, therefore, shows a profit of £411 as against profit of £56 made from wheatgrowing." (Secretary, S. Bowden.)

Attendance, 19.

Messrs. R. Currie and E. Day reported on the Riverton Conference.

KING ISLAND MELILOT.—Mr. Day said a field of this fodder plant had provided his cows and sheep with excellent pasture, and although it had a strong—not offensive—odor it had not tainted the milk. The difficulty of it, he said, was to reap a crop of barley without getting the seed. Barley merchants objected to it for malting purposes. Mr. L. George said that chaff merchants objected to hay containing it, although he thought it uninjurious to animals; he thought the smell was the chief objection. **Strangles.**—A member asked:—(1) “What is the best treatment for a horse suffering from strangles which had no swelling under the jaw and had difficulty to breathe?” Reply—Obtain a nosebag and pour hot water and turpentine on bran and place on animal for a short time. Rub a mixture of 1 turps to 2 heavy oil under jaw, which helped to bring up swelling. Other questions discussed were:—(2) What is the best method to eradicate warts from heifer’s eyelid? Reply—Apply castor oil or milk from the Sow thistle. (3) Is it advisable to cultivate stubble land dry to be cropped or leave until wet conditions? Reply—The general opinion was that early working was no benefit, but burning off and working immediately under damp conditions gave the best results if the land was not of too hard a nature. (Secretary, C. Currie.)

WHEATS FOR THE ROSEWORTHY DISTRICT.

[Paper read by Mr. J. Eden at the March meeting of the Roseworthy Branch.]

In latter years, the varieties grown in this district have changed considerably, taking the place of those that were grown a few years ago. This is accounted for by the fact that this district was chiefly a hay growing centre and at the time it was the opinion of many that harvesting grain on a larger scale would be an unpayable and unsatisfactory proposition.

Then there came the time when hay markets slumped and growing for grain was considered much more payable. Subsequently farmers turned more attention to reaping wheat and it was soon proved that Roseworthy could grow wheat crops equal in yield to any district in the State. In the hay growing period such wheats as Huguenot, Tuscan, and Indian Runner were favored, having an advantage over other varieties in weight and height, which are the main assets in growing hay for market. Almost all prolific hay wheats are poor yielders, so wheats were sown that yielded better and at the same time were suitable for cutting for hay. This district has advantages over most others in being able to grow wheat for grain as well as hay, so that what is needed is a dual purpose variety, then the farmer may use his discretion, whether he cuts his crop for hay or reaps it for grain. In discussing suitable wheats for this district, new varieties have come into prominence in the past few years and now the most suitable varieties appear to be Sword, Ford, Nabawa, Felix, Waratah, Sultan, and numerous others. Most of them have the virtues of making good hay as well as being prolific yielders.

The varieties now sown come under two groups—Macaroni wheat, of which Huguenot and Indian Runner are species, and the “Vulgate” group under the name of common wheat, which includes practically all the varieties grown in this district. To return to the most suitable wheats in this district, some varieties have not received the popularity that they had a year or so ago; the only clue to this answer is the inclusion of a new variety—Sword—which has forced out inferior competitors. Sword is worthy of first place in this district, and it can hardly be bettered as a dual purpose wheat.

It is advisable to sow several varieties; depending on the area of land available. While harvesting one plot, the other is ripening. Sow early, mid-season, and late varieties, to have a chance of reaping at the right time. A season may not suit some varieties; also, choose wheats for the condition of the land.

On the chart published below is described some of the characteristics of the varieties most suitable for the district.

DETAILED DESCRIPTION OF

Variety.	Pedigree or Source.	Germination.	Stooling Property (Good hay Wheats are not Good Stoolers).	Growth.	Season.	Freedom from Disease.
SWORD	Sultan x Ford	Medium	Fair	Strong	Medium Early	Resistant
FORD	Fancy x Crossbred 53	Medium	Fair	Strong	Medium Early	Very Resistant

WHEAT VARIETIES.

Lodging.	Shattering of Grain.	Head Straw.	Hay.	Grain.	Quality Grain Milling.	Remarks.
Very good	Fair to good	Light color, fairly high, long head, 2 or 3 grains	Excellent heavy	Light and long in color. Pro-lific yielder	Fair to good	Not properly fixed
Good	Fair to good	Do.	Very good	Very good yield	Good	A good reaping wheat
Inclined to lodge	Good	Do. Not as long as above 2	Good	Yellowish and long, good yielder	Only fair	Grain cracks easily, poor bread wheat
Inclined to lodge	Good	Do. Little shorter (x) than one above	Good	Yields well	Fair to good	Has done well in this district. Good wheat for dirty ground
Good	Shakes a little	Dark color, short nugget head	Poor fodder	Plump heavy and dark grain, oval shape, good yielder	Fair	Several sterile spikelets in this district. Threshes well. Copes well with weeds
Inclined to lodge	Good	Thick straw	Good heavy hay—not in mallee districts	Good yielder	Fair	Strong grower for weedy paddocks
Good	Inclined to shake	Hollow pithy straw, yellow tapered head of medium length	Good	Light color, plump, and oval, yields well	Excellent	Spikelets shatter readily
Lodges easily	Good	Darkish color, short beard, 3 or 4 grains	Good	Second class, yellowish, points at ends but well rounded	Fair	Worst point is lodging; has solid pithy straw
Good	Good	Short strawed, dark, small compact head, 2 or 3 grains	Not any use for hay growing	A good yielder	Fair	A wheat that reaps better than looks.
Stands up well	Good	Short, small, and compact head; short straw	Do.	Excellent yielder	Fair	Coming wheat, suit red ground best. Many shoots come from one root

TRURO (Average annual rainfall, 19.95in.).

April 16th.—Attendance, 17.

FARM ROUTINE.—Mr. M. Rice read the following paper:—"Commencing from mid-April.—This year, owing to the early rains, farmers should be preparing for sowing oats and Cape barley for early feed. Wheat should not be sown too early, mid-May to June being quite early enough in this district. Seed should be graded or put through the winnower again. Do not sow too many varieties of wheat—three to four kinds on the average farm is quite sufficient. The end of June should see the finish of seeding, except sowing barley for seed. Seeding completed, most farmers allow their horses a fortnight's spell before commencing fallowing. Have early fallow, but do not plough the ground while it is too wet, because it then sets hard and does not become properly aerated. Deep ploughing is not necessary, 3in. is adequate; if fallowed to 6in. clay is turned up, which does not assist in yielding good crops. Harrow the fallow immediately after ploughing and allow the ground to remain until weeds begin to sprout, then cultivate with a stump jump cultivator in preference to a spring tooth or combine. The first cultivation should be the deepest, then a little shallower at each subsequent working. Most farmers keep sheep, and after the fallowing is completed it is necessary to prepare for shearing. Hay cutting starts about the first to second week in November, and much depends on the variety of wheat sown. Bluey has been a good hay wheat. Out the wheat as the crop turns yellow, allowing a little grain to form to improve the feeding quality of the hay. Hay should be carted 10 days to a fortnight after cutting, when the hay should be thoroughly dry. In building the stack, always keep the middle filled to throw out the rain. When the hay is carted, oats are ready to strip, and should be reaped immediately they are ripe or they will shake out and be lost. After cleaning the oats, shoot them out in the barn, then the mice will not ruin the bags or damage the oats to any extent. By the time the oats are reaped barley is ready, and finally the wheat is ready for the stripper. The standing crop is the best place from which to pick seed for next season. After harvesting is completed straw has to be carted to cover the haystacks, and there are always a few sheds, &c., that need covering. It is advisable to build a few straw stacks for shelter and fodder for stock during winter. Then comes the farmer's slack time, which is filled up by fencing, dam cleaning, and the numerous odd jobs that need attention. During March seed wheat should be prepared. Dry pickling can be done at any time, but when bluestone is used, the seed must not be pickled until almost required for sowing. Dry pickling is better than the old method, because the wheat germinates more quickly, it is a better fungicide and can be done at any time. The old wet pickling method often meant doing it after tea, when a farmer's day's work ought to be finished." (Secretary, L. Davis.)

YORKE PENINSULA DISTRICT.**SOUTH KILKERRAN.**

March 27th.—Attendance, 7.

DESTRUCTION OF PESTS.—Paper read by Mr. W. A. Heinrich:—"The pests that mostly concern farmers are rabbits, foxes, rats and mice, weevil, blowflies, common houseflies, sheep lice, fowl lice, and tick. Little need be said about the damage caused by these pests, and it would be difficult to estimate what they cost the Australian producer annually. The means of destroying them vary according to the conditions in which they exist. In this district the best method for killing rabbits is to fumigate the burrows after the rabbits have been chased in by dogs. There is no need to buy expensive fumigators, for most farmers have either a car or a tractor. With a length of flexible tubing slipped over the exhaust pipe and the other end inserted in the main burrow and covered in with loose dirt, the engine is started and run at a speed a little faster than idling. As the gas rises from the other openings, they, too, are closed up. By doing this, all the air is forced out and the burrow filled with carbon-monoxide gas; death is certain to anything that happens to be in there. The next procedure is to destroy the burrow. I recommend where possible to plough to a depth of 12ins. to 15ins. with an old three-furrow plough on a tractor or a single furrow with horses. Even though this method does not disturb the deeper holes, it leaves so much loose dirt on top that outside rabbits seldom find them again. The fox is more elusive, and unless seen going down the burrow, digging, fumigating, or swamping may be a waste of time and water. Although there are quite a number seen at day, anyone who has not been out at night with a spotlight has no idea how many are actually roaming around. They do a certain amount of good when mice are bad, but unfortunately they are not satisfied with that diet, and lambs and poultry usually make up the desired meal. Where the country is reasonably clear enough to drive a car, spotlight shooting is easily the best way to thin them out. Poisoning is quite effective, but must be understood and carried out with care; baits left lying around are dangerous to livestock. A good idea is to drag a trail across a paddock with a frosh sheep's liver and at intervals bury an egg dosed with strychnine. Rats and mice can be poisoned with less dangerous stuff, but this method is not very desirable in a house or in sheds where feed is kept for stock. When hay is kept for any length of time a mouseproof enclosure will save a lot of waste, and where a mouseproof barn is not available and space not too limited, bags of grain should be stood in rows, two high, with sufficient room for cats to get between the rows. This prevents rats or mice from nesting there. I have tried stacking both ways, and the loss of grain and torn bags is far worse in the close stacking. Have a small opening in the door or wall for cats to go in or out when they like and a good supply of fresh milk available and not too much scraps from the house when mice and rats are plentiful. Weevil do not affect the farmer seriously unless he holds grain for long periods. The most effective way to protect seed wheat is to dry pickle it. Fumigating stacks to rid them of weevil has been carried out with a fair amount of success. The blowfly trouble is a very serious one and not so bad as it was some time back; every care must be taken to destroy by burning or burying any dead animals. This also upholds the theory of fumigating rabbits in preference to poisoning. Crutching sheep with shearing machines, say twice a year, minimises the trouble to a great extent. The common house fly is one that requires a lot of keeping down. Fowls are very useful in this respect, and although they are undesirable in the stable so far as the chaff is concerned, the good they do there more than makes up for it, as they are continually scratching the manure about and thereby disturbing the breeding-places of flies. As a precaution against lice in sheep it is necessary to dip. The same solution is also very useful for destroying flies and fleas in sheds, &c., also fowl lice. As fowl tick live in the cracks of wood in the roosts, &c., and only attack the birds at night, all woodwork must be soaked with waste oil and kerosene." (R. Hasting, Secretary.)

FORTY-THREE YEARS AGO.**STRIPPER OR REAPING MACHINE VERSUS TWINE BINDER AND BAGSHAW'S HEADER.**

The following interesting paper, extracted from the first minute book of the Arthurton Branch, and presented by Mr. J. Koch on June 20th, 1891, was read by Mr. T. Howlett at the February meeting of the same Branch:—"All farmers in this district have cause more or less to sorrowfully remember the harvest of 1890 because of red rust, and as this disease was again making itself very conspicuous just before last harvest I determined upon becoming the owner of a 'Hornsey Twine Binder' to

take off as much of my crop as possible for hay. I purchased the binder at a cost of £65, cut all my hay with it, the result of which my hay chaff commands a sale of about 7s. 6d. per ton more than if cut with the ordinary mower. I confess that I consider the mower a thing of the past after having used the binder, which is really a labor-saving as well as a thoroughly economical machine, does away with the rake, no cocking required, while I believe the greater advantage is apparent in the carting. This can be gone on with in any weather; in fact, a wind is preferable for throwing sheaves, whilst for loose hay the wind is a great inconvenience, and lastly, a stack is much more easily reared, providing the right way for building is adopted; also when properly finished is much more proof against winter rains than a stack of loose hay, and to those who have an eye to the beautiful or neat appearance of their stack yard the sheaf stack is much more symmetrical than the other.

After having finished cutting the hay, I put the binder into a very nice even crop of Steinwedel wheat, just as it was on the turn for ripening, just 12 days before the balance was fit to reap; some of the heads which were not quite so ripe, and others were yet doughy. I cut 10 acres with the binder, which, when cleaned up, realised 191bush. of a sample of a splendid plump grain of a nice bright color and much more productive if used for seed, because of no broken grains as we generally find among wheat when reaped by the stripper. I reaped the same number of acres of the same crop with the stripper. I used the binder on the outside, going all round the piece then the middle of that which was left I stripped. The crop was to all appearances precisely the same, if not better than what I cut, but after winnowing and bagging up I discovered I had only 166bush. 47lbs., being a little over 2bush. on an average per acre less than I realised from the binder. There is no necessity to go into details on the working or cleaning up after the stripper, but as some are probably unacquainted as to the mode in which the headers work I will endeavor to explain the method as briefly as possible. I have my horse works made stationary to my chaffcutter, so that I fixed the header on the opposite side to that of the cutter, the horses working or drawing in the opposite direction. I drew the ground plan some time beforehand, so that I arranged my stack of sheaves as conveniently close to the header to allow of operating room, and also a stool for a stack of the sheaves after having passed through the heading machine. Having all in readiness for a start, with five assistants, we commenced operations, one man throwing off stack to the header, another handing on to the feeder who, after having pressed the sheaf home for the header to do its respective work, threw the sheaf to a fourth man, who tossed it on to the stack, where there was one other beside the builder. The wheat is driven with great velocity out into a heap from the header ready for the winnower. Messrs. Bagshaw state that two horses drive this machine, but I found it too much for two to keep going, so I hooked on a third, which made comfortable work of it. I am of the impression that a Bagshaw header is more to our purpose than is a steam thresher for the following reasons:—The cost is in the first place £14, which is within reach of any practical farmer and can be worked by ordinary horse works—the price is a mere bagatelle compared with that of a steam thresher. There is no risk of danger of fire raised by sparks, no water required for feeding, which sometimes is an item to be considered in summer, and lastly, when the header is used, the strings are not cut or broken, leaving the straw so much better to put again in the stack ready to be taken at any time to be cut up into chaff. As the straw is cut when green, this makes really a very good feed for cattle or horses; my own horses eat it well when chaffed. The work of chaffcutting is considerably reduced with sheaved hay, for I find I can feed quite comfortably without the aid of anyone, which I cannot do with loose hay, while the chaff is cut much more evenly, because the straw in a sheaf is laid straight. *Re* cost of twine and oil per acre, Mr. Koch stated, in answer to a question by Mr. Mills, that the total cost for both was about 16d. per ton. He recommended Manilla twine for the binder."

WESTERN DISTRICT.

OEDUNA (Average annual rainfall, 10.16in.).

March 6th.—Attendance, 11.

The monthly meeting was held at Mr. C. Kloeden's residence. Congress resolutions were discussed. Mr. W. Pfeiffer read a paper—"Tractors on the Farm." Mr. E. A. Hastings was presented with a Life Membership certificate of the Agricultural Bureau. (Secretary, E. R. Pfeiffer.)

CHILPUDDIE ROCK.

April 4th.—Attendance, 12.

Members discussed the best methods of farming successfully in this district. It was considered that the farms should be between 2,000 and 3,000 acres; at present the average farm was about 1,100 acres, and it would not pay to subdivide a farm of that size into sheep-proof paddocks for the number of sheep the farm would carry. Wheat should be grown on fallow only, and then only once in four years. To fallow successfully sheep were essential, because the soil would drift if cultivated too often. Members were of the opinion that they would be able to work a farm of between 2,000 and 3,000 acres in conjunction with sheep with the same plant as was now necessary on their present holdings. (Secretary, H. Brown.)

LAURA BAY.

March 13th.—Attendance, 14.

HARVEST REPORTS.—The following yields were reported:—A. J. Bowell, Nabawa, 4½bush.; A. R. Lowe, Florence, 5bush.; C. Collins, Quality, 6 bush.; J. W. Blumson, Waratah, 6bush.; W. L. Edson, Canberra, 10bush. Florence, 8½bush. Nabawa, and Rancee 7½bush. The best samples were: N. S. Morrison, Waratah; A. R. Lowe, Nabawa and Florence; W. L. Edson, Rancee; C. Collins, Quality. (Secretary, W. L. Edson.)

WARRAMBOO.

April 13th.—Attendance, 8.

IS THE AGRICULTURAL BUREAU WORTH WHILE?—Paper read by Mr. F. Chilman—"The Agricultural Bureau is a valuable farmers' organization, for the following reasons:—There are 336 Branches, with a membership of 7,999. Such a State-wide organization could do a vast amount of good if all members pulled together. The members of the Advisory Board will always give serious consideration to any matters sent in to them. The annual Congress in Adelaide deals with all subjects brought up by the Branches throughout the State, and local conferences deal with all local matters. These are referred back to the Advisory Board for consideration. Members often fail in not taking enough interest in local conferences, it is up to all Branches and local members to take an interest in these and see that they provide material for discussion and papers to be read. Our Bureau organization is the envy of other States, and yet interest is often lacking in local centres to make it worth while. It is the duty of all members to join in the discussion and see that interest is maintained."

Mr. O. J. Murphy read a paper on "Harrows." He said land prepared with the harrows and drill grew as good a crop as that in which the combine was used. The former were lighter on the horses, but took an extra man to work both together. Where share points were bolted on to the harrows it was excellent for killing weeds when small. Members favoured having the ground damp when harrowing. (Secretary, F. Chilman.)

EASTERN DISTRICT.

MONARTO SOUTH (Average annual rainfall, 14in. to 15in.).

February 17th.—Attendance, 16.

FIRST AID.—Paper read by Mr. M. Kuchel:—"There should be a first-aid kit or cabinet on every farm, thus acting as an emergency in case of accident, especially where a farm is some distance from a doctor. First aid can then be given. After this is done, and should the accident be of a serious nature, the patient can be taken to the nearest doctor without delay. *Points to Bear in Mind.*—(1) Blood from an artery is bright red and flows in jets. When blood flows from an artery, prompt action is required to save life. (2) Blood from a vein is dark-bluish in colour and flows slowly; the flow in veins is just the reverse from arteries. Stoppage of bleeding is the first point to be attended to if it is serious. Bleeding may be from an artery or a vein, or both. The readiest means of stopping bleeding is pressure, which may be carried out by tight bandaging above and below the wound, and placing a pad and bandaging over it (the pad must be clean lint or folded cloth), or for severe bleeding a tourniquet may be applied to the wound or limb above the wound. This severe pressure should be removed as soon as possible. For ordinary wounds a simple pad and bandage over it is usually sufficient to control the flow. *Broken Bones (Signs of).*—Motion at the part, a crackling sensation on moving broken ends, alteration in shape of limbs, often shortening. *Treatment for Some of the Important Breaks.*—Always apply splints before lifting or carry the injured person. Dangers are of pushing the broken ends through flesh, blood vessels, nerves, or internal organs. (1) For the hand—Apply splints, bandage and support in a sling. (2) Legs—Apply splints inside and outside and bandage. (3) Forearm (wrist)—Apply padded splints to back and front from hand to elbow, holding the arm extended with the thumb pointing upwards, support in a sling. (4) Upper Arm—Bend arm and apply roller bandage to hand and forearm, splints to back and front of arm, sling the forearm. *Dislocations.*—(1) Elbow—Simple extension, the elbow being kept straight, with the patient seated on a low stool or on the ground; place the knee in the bend of the elbow and taking hold of the patient's wrist, pull steadily and firmly, at the same time bending the arm gently, and the bones will in most cases return to their places without difficulty. (2) Fingers.—These are difficult to manage, but the general extension of simple principles is all that is usually applied. (3) Shoulder.—The common form is into the armpit, the shoulder is flattened, the head of the bone may be felt with the fingers, and the arm cannot be easily raised, even with the shoulder. Treatment: Have the patient lie down and sit directly behind him, place one hand upon the shoulder to fix it, then raise the arm from the side and straight up by the patient's head, until the bone is thus elevated into its socket. Another method is by the patient's self, by attempting to lift a gate—one that is fixed—placing the arm over the gate, so that the armpit rests on the gate and then lift slowly. (4) Dislocation of Wrist, Knee, or Ankle.—These are mostly accompanied with a fracture of one or both bones of the involved joint, and the services of a good surgeon are indispensable or a wrist-strap for keeping the wrist in place. *Foreign Bodies in the Eye.*—These should be removed as soon as possible; do not rub, this only increases the inflammation. If the injury is caused by caustic, strong acids, or salt, drop sweet oil into the eye. When lime, ashes, dye stuffs, or tobacco is the offending object, cream or sour milk is the best application. When sharp minerals, paint, sand, dirt, and the like get into the eye, apply white of an egg. If small particles cannot be removed by the above means, the upper lid should be turned inside out by taking the eyelashes between the finger and thumb, then turning the lid upperwards over a probe or match-stick; the foreign substance may then be wiped off with the corner of a clean handkerchief. *Burns (Severe).*—Wash with picric acid, exclude air. Any of these local applications is recommended—(1) Carron oil, a combination in equal parts of linseed oil and limewater. (2) Carbolic acid and olive oil—1 part of the acid to 12 parts of olive oil. (3) Soap—Moisten white or brown soap in water, place thickly on linen, and place on the burn. (4) Flour or Starch—Spread thickly on the burn. The remedies that have been given are for the most frequent accidents where first aid can be given without the aid of a doctor. The application of a dirty dressing by dirty hands to wounds is frequently the means of spreading disease instead of stopping it; use antiseptic washes and the thorough and skilful use of water and soap is of far more use than misapplied remedies." (Secretary, C. Altmann.)

PRUNING COMPETITIONS.

A meeting of the River Murray Pruning Competition Committee was held at Barmera on May 2nd, when representatives of B. rri, Ramco, Waikerie, and Barmera attended to receive the annual report and to discuss the details of the forthcoming competitions.

The Secretary (Mr. J. J. Odgers) stated that in the 1933 competitions there was an increase in the number of competitors at Cadell, and that Block E substituted for Renmark.

There was a greater number of candidates for the championship last year than for many years, there being 17 in the vine and 15 in the tree sections. Trophies were donated by the Royal Agricultural and Horticultural Society, the Dried Fruits Board, Mr. W. Langdon Parsons, The Adelaide Chemical and Fertilizer Coy. Ltd., Nitrogen Fertilisers Pty. Ltd., and the Wallaroo-Mount Lyell Fertilizer Co.

Mr. R. Isaacson, Waikerie, won the trophy for the highest aggregate, and also won both the vine and fruit sections. There was keen competition throughout—Waikerie, Renmark, Cadell, Mypolonga, Berri, and Moorook being represented in the placed positions.

The Langdon Parsons trophy for the highest aggregate in the local competitions was won in the first year by Mr. E. A. Liddicoat, of Moorook. The trophy (silver cup) will ultimately be held by the competitor holding the highest aggregate over a period of three years. Mr. Liddicoat has been presented with an inscribed silver medal indicating that he was the winner of the Langdon Parsons cup for the first year in which the cup was donated for competition.

The financial statement showed a credit of £6 19s. 11d.

In arranging details for this year's competition it was decided to ask again for the services of Mr. E. Leishman (Horticultural Instructor) as judge, and that local committees appoint two consultative judges to assist him. Competitions were then arranged for Cadell (June 26th), Waikerie (June 27th), Moorook (June 28th), Barmera (June 29th), Berri (July 3rd), Renmark (July 4th), and Berri (championship) on July 5th. The date of the competition at Mypolonga to be arranged in consultation with the judge.

The rules governing this year's competition will be practically the same as last year.

CONSTRUCTION OF AN IRRIGATION AREA FOR THE PURPOSE OF FODDER PRODUCTION.

[Paper read by Mr. F. Suter at the March meeting of the Overland Corner Branch.]

The remarks in this paper are confined to inundated lands adjoining permanent water courses. The land usually being of a rich nature, has a decided advantage over the higher land which incurs a much greater expense in primary construction. The river frontage lands in this district are usually termed inundated land, although comparatively speaking, the medium low-lying land is only flooded once in 3 years. The higher land may be flooded with a very high flood which rarely occurs, high floods usually being from 7 to 10 years apart. Should the high flood occur every 7 years and flood the fodder block the owner would benefit because lucerne being the best fodder under irrigation needs replanting after 7 years intense cutting or feeding off. Should the beds become flooded at any time this will cleanse and fertilise the land to such an extent that the improvement in the growth of fodder will be noticeable after replanting.

Referring to the river flats, the growth of any summer fodder which may be grown is prolific just when it is most needed, i.e., when all the high land feed has dried off or blown away. There is also much higher land as a rule quite close to the main permanent watercourse. It would be quite safe to say that this land will not grow weeds or herbage under natural conditions. This land if placed under irrigation grows an abundance of good fodder economically. More so on account of its nearness to watercourse if planted with lucerne owing to the roots penetrating the subsoil to a great depth in search of moisture for its growth.

LAGOONS.

The very low-lying land, commonly known on the Murray as lagoons, dry out in dry seasons. A number of owners of these lagoons try irrigating or flooding a wheat crop on other fodder owing to the shortage of feed through the dry season. This is often done successfully, but frequently a larger percentage of the growing crop—if not the seed—is destroyed through an excessive amount of water laying there for a

lengthy period. It is quite possible to grow a crop of wheat on these lagoons with two irrigations through the summer months. The holders of these lagoons will usually buy a really good pumping plant for the flooding of same and expect to irrigate this low-lying flats because it looks level to the naked eye and has been flooded when the river overflows its banks.

IRRIGATING.

In commencing operations on these lagoons the pump is erected at the water-course at the nearest possible point to the lagoon. A few furrows are ploughed to the lagoon and continued on around the edge of the flat. The seed is sown and the pump set going, and immediately trouble begins. It is usual to have an assistant at this operation who usually tires first. However, both run along the plough furrows stopping up break-aways until at last the water reaches the spot where one begins distributing same over the lagoon. After some time it will probably be found that the water has broken away, and making for the lowest place in the lagoon. Now it is found that the lagoon is not quite so level as it was thought to be, and repeated attempts are made with shovels checking it in one place and another; but the water will have its own way if not governed. Too often the person doing the irrigating gives up in despair and says, "Let it go, if that is irrigating I am having no more of it; she will flood herself with this stream as the River has flooded times out of number before." Nevertheless, they repeat the operation during the next drought year on the same principle. They do not think of making any check banks to govern the water or make any provision for draining off excess water. The excess water would not be there if check banks were there to control the water. Nor do we think of converting the land abreast of the site where the pump is erected into a patch of permanent fodder beds. The plant is left to rust and is buried with leaves, bark, &c., and the pipes are taken away and used for rails around the horse yard.

In the construction of fodder beds under any system of irrigation, provision should be made to drain off any excess water. It is difficult to explain why fodder is not grown more extensively under irrigation, even if only a small patch on each holding. It is not the climatic conditions, for they will grow more fodder than can possibly be used or needed.

CULTIVATION.

In choosing any frontage on the River Murray with inundated land first select the higher site which is most convenient, especially if it can be connected with a lagoon. Make a rough survey of the high land already chosen and decide upon the most suitable sized pump required to irrigate. The land should then be thoroughly grubbed.

The next operation:—With a good strong single furrowed plough—one that will plough 12in. deep—plough the land and harrow. If necessary, after harrowing, grade off all small hills and fill hollows, leaving the surface even.

TAKING THE LEVELS.

The next performance is taking levels (in this case not with a naked eye). Use levelling instruments from which will be found the layout of the block. The highest point will be where the pump will have to deliver the water to and from where the channel will gravitate water to irrigate the beds. On the levelling operations the fall, if any, will be found out. Then the beds should be laid out with sighting pegs. Gather to pegs two plough furrows, use a grader to throw up banks, or a road former can be used. Whilst throwing up check banks use the same method on the site of the channel, gather enough earth together so that the channel can be banked well above the level of the surface of the beds.

When the banks are all thrown up, grade the beds, which should be half a chain wide and uniform. Great care should be taken in the grading of beds. The deep ploughing in the first place should be sufficient to enable completion of grading. Care should be taken not to remove all surface soil which would not be done if the system of laying out has been correct. If the grade in the beds is too steep—which will be noted in the levelling of the block, change the angle of the beds to reduce the grade. If unable to reduce the grade sufficiently, try terracing on the contour of the hills. No trouble should be experienced in keeping the beds half a chain in width. When paving the terrace beds, it is possible to have a slight fall from the outlet pipe; if, on the contrary, there is a slight rise from the outlet pipe and the bed is graded ready for planting, plough furrow through the centre, this will allow excess water to drain off to the channel. A 4in. to 6in. fall to the chain in beds is good watering.

CHANNELING.

The channel commences from the outlet of the delivery pipe. About 10yds. of concrete channel should be laid here to prevent any washaway of earth from the swirl of water as it is thrown from the delivery pipe. After the few yards of concrete channel, an earth channel is good enough for the main in almost all cases. The main

channel is all that is necessary and should have not more than a lin. fall to chain when excavated. The size of the channel depends on the size of the pump. The channel dimensions to serve most cases on a home irrigation patch would be 3ft. 6in. wide, 15in. deep, and 15in. wide in the bottom, excavated under 3in. of the level of the surface of the beds, 12in. above, with a shoulder not less than 2ft. 6in. wide. The most suitable outlet is a pipe, not less than 4ft. in length. In putting in outlet pipes, keep them 3in. to 4in. up the wall from the bottom of the channel. A hollow mallee is very serviceable for this purpose. If there is a fine surface on the beds they are then ready for planting.

THE BREEDING AND CARE OF FARM HORSES.

[Paper contributed by Mr. E. W. Pearson, of Brinkley, at the March meeting of the Murray Bridge Branch.]

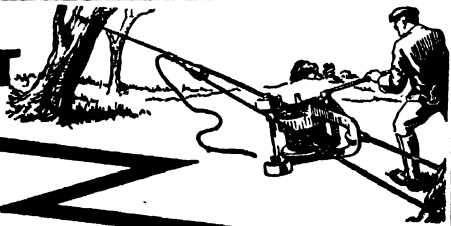

The subject under discussion is one that every tiller of the soil should be deeply interested in. The horse is by far the greatest asset on the farm, and too much care and attention cannot be given to enable him to carry out the work which is demanded of him. In recent years arguments have been brought forward in favour of mechanical power on the farm; quite a number of farmers have tried it out and have—after paying dearly for their experience—reverted to horse power, which fact, coupled with the increased demand and the higher prices ruling for horses to-day, is sufficient to lead one to say that the horse has regained his position on the farm which is his by right. The first question that a farmer has to consider is that of supply. Naturally, a farmer to begin with has to purchase his requirements, and should include among his purchases a few mares of a suitable type for breeding purposes. This with a view of maintaining the future strength of the team. It will be generally agreed that it is more satisfactory and more profitable for a farmer to breed all the horses he requires for his purpose; the purchase of horses in a saleyard often proves disappointing.

SUITABLE BREEDING STOCK.

The Sire.

This is a matter that is of the utmost importance if a suitable type of farm horse is to be secured. Unfortunately in the past there has been a tendency on the part of farmers to breed from any class of mare that would produce a foal—irrespective of class or type—with the result that quite a number of horses seen on farms at the present time cannot be classed a suitable type of farm horse, and I strongly urge every breeder of horses to do his utmost to raise the present standard by discarding

TEARING THEM OUT

Is the regular job of the Monkey Grubber. In fact it was born to the work.

TREES and STUMPS, it matters not, they are torn out with roots intact, a thorough job quickly done. Run to the job like a barn truck, and worked in the same manner as a boat is rowed. It develops the power of 250 men, progressively applied, and always under perfect control.

In any position, so long as the operator has space for a footing, the machine is efficiently worked. An Automatic Gear allows a load to be hauled or released at will. Besides the great power and portability there are embodied other labour saving features, such as special rope couplings, rope shortener, snatch block, etc.

Agriculturalists in Australia, New Zealand, Great Britain, South Africa, the Americas, as well as Planters in India, China, Central Africa, Fiji, the East and West Indies, recognised its merits and applied its help.

THE "MONKEY" GRUBBER

is fashioned from material mined and made within the Empire, by Empire craftsmen, to assist with the fast and efficient development of Her Soil's resources.

any animal for breeding purposes that is unlikely to bring about that result. The most popular type of horse for farm purposes to-day is the Clydesdale, and for general all-round farm work can be recommended as being capable of doing any work on the farm. The point to be emphasised so far as breeding is concerned is to secure the service of the very best sire available. He should be a stud book horse if possible, which is a guarantee that his breeding is good; failing that he should at least bear a certificate of soundness. Breeding from unsound sires cannot be too strongly condemned, and the suitable class of stallion will never fully come into his own until the registration of all stallions is made compulsory, which measure is to be adopted in the near future.

The Brood Mare.

It is not necessary to describe the points of a suitable mare, because they are generally well known to the average man, but there are a few important matters which should not be overlooked to ensure a suitable mare becoming a successful breeder. To secure a reliable brood mare, she should possess a good, sound constitution and should be mated for breeding purposes at an early age, say at three to four. This method does not always prove successful, but in many instances a mare, unless bred from when young, proves very unreliable as she grows older. Another point to consider is the condition of the mare at the time of service. Always try to avoid a mare carrying too much condition—a thing which often happens in the spring of the year if the mare is not working.

CARE AND MANAGEMENT OF THE HORSE.

The care and management of the horse is a matter of great importance, because the efficiency of the horse depends very largely on the treatment it receives from its owner. Actually the care of the horse from a breeder's point of view begins before the foal is born. The in-foal mare, in order to produce a strong and robust foal, must receive treatment that will enable her to bring about that result. A mare during pregnancy can be worked at any ordinary farm work with benefit to herself and her unborn foal, assuming that this is done reasonably and intelligently. Good feeding, of course, is also necessary, always bearing in mind the fact that the mare has to support the life of the foal as well as her own. The practice of working the mare can safely be continued with care up to within a few weeks of foaling if necessary, but be careful to avoid any heavy lifting or work in shafts. At this stage it is advisable to separate mares due to foal and place them in a small paddock by themselves where they can be kept under constant observation, and when the time for the birth of the foal arrives, it is advisable for someone competent to give assistance to be on hand, for a little assistance at the critical moment may mean all the difference between a live foal or a dead one; probably the life of both mare and foal may be saved.

In the case of a young mare with her first foal, the mare's udder will probably be swollen, and if she is inclined to be restless, the foal will experience a difficulty in getting hold of the teat. If such is the case, tie up the mare and assist the foal, and having once sucked, there should be no further difficulty in that direction. A foal at birth is subject to bowel trouble, and if there are signs of costiveness, 1 tablespoon of castor oil will be of benefit. If a mare is required to work during the time she is suckling a foal, this can be done without injury to either, after the foal is 6 or 8 weeks old, but must not be overdone. Neither should the mare be separated from her foal for a longer period than 3 or 4 hours. If the mare is working, never allow the foal to follow its mother; it will not only prove a hindrance to the team, but is also very liable to receive injury.

At this stage if the foal is to be separated from its mother, tie it up, and if time will permit learn it to lead, and half the work of breaking in will have been accomplished when that time arrives.

At from 4 to 5 months old the foal should be weaned. This is perhaps the most critical period in the life of the horse. The foal should be separated from the mare and placed in a loose box or a yard that is foal-proof. It should have free access to water at all times and be fed at regular intervals on good nourishing food. This practice should be adopted until there is sufficient green feed in the paddock to enable the colt to look after himself. To enable a colt to grow and develop into a desirable animal, he must be fed, and fed well. No matter how he is bred, always bear in mind that "feed is half the breed," and from a utility point of view it may be considered the larger half.

At 2½ years a colt should be ready for breaking in. He should be carefully handled and mouthed before being put into the team, and should not be asked to do more than three hours' work a day for the first few days, especially if he shows signs of being a free worker. Remember that his shoulders are tender, and if overworked for a start may develop sore shoulders which may cause trouble for the rest of his life. If a good, well-fitting collar is provided, and the shoulders are not allowed to become overheated, no trouble should be experienced, but as a precaution it is advisable to bathe the shoulders in cold water, with a handful of salt added when the collar is taken off.

It can now be assumed that the horse is fairly started on the road with his life's work before him, and will be subject to all the ills that horseflesh has to contend with, and there is no doubt that at least some of the common ailments that the horse is subject to can be avoided if proper precautions are taken. Bear in mind at all times that "prevention is better than cure." If a farmer wishes to advertise his farm, he can use no better method than by paying strict attention to the breeding and care of his farm horses.

SOUTH AND HILLS DISTRICT.

HARTLEY (Average annual rainfall, 15in. to 16in.).

January 31st.—Attendance, 14.

VEGETABLE GROWING.—Mr. H. Brook read the following paper:—"If the land is prepared and well manured with horse manure, and weeds kept down for about 12 months before sowing the seeds, vegetables can be grown without very much trouble. Protection is needed from hot and cold winds, frost and hail. Our soils are fairly rich and easily worked. Most gardening is done in winter, because well water is salty. Dig deeply and keep the land well tilled before and after seeding. A list of the best plants to grow is as follows:—Cauliflower, cabbage, red beet, turnips, carrots, silver beet, and red radishes. Plant broad beans around the edges, because they grow to a fair height and shelter the other plants. Make the rows 18in. apart. Never grow the same crop in the same land two years in succession unless it is well manured. A little superphosphate will be beneficial to quick growing plants."

TRAINING A SHEEP DOG.—Paper read by the Hon. Secretary (Mr. D. C. Harvey)—"The recognised sheep dog of the world is the Border Collie, a breed highly recommended for its steadiness in driving a few sheep and ability to handle large mobs. It also has had marked success in field trials in England, Australia, and New Zealand. Make certain that the pup is bred from reliable stock and proved workers. A sheep dog crossed with a silent heeler cannot successfully work sheep. There are two good breeds of sheep dogs in Australia—the Border Collie and the Kelpie. The Kelpie has more dash than the Border Collie, and naturally drives the sheep faster. Although quite a good dog with large mobs, it does not meet with success in the trials. Allow the pup plenty of freedom, do not knock it about, or it will become nervous. Good feed at this stage is necessary; it means much to the growth and constitution of the dog. Plenty of new milk with cooked meat daily should be the diet, with raw meat three times a week. **Training.**—The most important part, at six months old, is to teach the pup to sit down. This is done by giving the dog a push down, at the same time saying 'sit down.' Then attach a cord 20ft. long to the pup, and allow it to run out from you. Give the cord a pull, the order to 'sit,' at the same time holding up your hand. After a few lessons the dog will respond readily to the command, which later on may be given by whistle instead of word of mouth. When the pup is sitting, make it stop there until ordered to 'get up.' Treat the animal with kindness and firmness at all times. This part of the training should all be done before the dog is taken near sheep. When old enough to work

sheep, use an old dog and round up a mob of about 50 sheep. Get them against the fence and stand back about 30yds. for a start; sit the pup down behind and then wave him out which way he is to go, and give the command 'get out.' When far enough round the sheep, whistle and make him sit down. This will make him approach the sheep gradually and drive them steadily to his master. Then make the pup sit behind you again, and wave him out the opposite way in the same manner. This will teach him to cast on both wings. It is best to walk in front of the flock and allow the pup to drive the sheep behind his master. Do not be disheartened if the pup makes mistakes. *Some Useful Hints.*—Treat him kindly but firmly, make him do as he is told. Never work a pup too long; 15 minutes is enough for a start. Do not expect big success for a start, persevere with the pup. Failure is often the fault of the master through expecting too much. A pup cannot be relied on until he is 18 months old. Never allow a dog to bite the sheep. Always make him work wide of the flock.''

INMAN VALLEY (Average annual rainfall, 26in. to 27in.).

March 18th.—Attendance, 9.

PASTURE DEVELOPMENT AND ROOT CROPS.—Points taken from an address delivered by Mr. R. Hill, District Instructor:—Improved pastures were an asset, but with good and methodical management the two combined made a financial success. Careful management assisted by subdivision brought about smaller paddocks, the growth on which was cut for meadow hay or ensilage. The stack silo was preferred to the pit. In the last four or five years farmers were finding out how to handle meadow hay to get the best results. With the cutting of hay it greatly minimised the risk of fires. Hand-feeding of sheep in the winter enabled one to carry a full quota of stock over the winter months, whereas prior to conservation of fodder, the surplus stock had to be sold after the spring months, when the markets were generally at their lowest. The possibility of growing root crops in this district was considered a sound and economical way of feeding livestock. Instances were given that 40 or 50 tons of mangolds could be grown per acre in some districts. These were eaten readily by pigs and cattle after being stowed, which greatly added to their usefulness, as they could be fed to livestock when green fodder was scarce. They could be grown successfully with about 4lbs. or 6lbs. of seed per acre planted in late spring. A liberal amount of manure with an additional amount of salt would greatly assist growth. Mention was also made of turnips and swedes, but grazing crops was considered the most economical way of feeding. Chou mollier is grown extensively in the South-East and could be grown successfully in this district. Seed should be sown at the rate of 2lbs. per acre. The feeding value was very high and the stalks and leaves were very palatable to livestock. One could reasonably count with success if sown in October or November. Sunflowers and Sudan grass could also be sown and grazed by livestock with beneficial results. (Secretary W. Mayfield.)

MILANG (Average annual rainfall, 14.97in.).

February 24th.—Attendance, 18.

EXPERIENCES OF THE PAST SEASON.—Mr. J. Bagley read the following paper:—“One of the most noticeable features during the past season was the absence of soursofs at harvest time on a piece of land very badly infested. The land was fallowed and worked during the year, and each working seemed to have no effect upon the weed; after every working the plants came up as strong as ever, until the last working—a harrowing in early June—and from then on they seemed to fade away, and at harvesting they showed no ill effect upon the wheat crop. It will be remembered at the time when the harrowing was done the weather was dry and warm with cold nights, being most suitable for weed killing. I had previously heard that there was a certain time when the weed could be checked with a working of the soil, and it now remains to be seen if they will come up as strong again in the coming year. *Smutty Wheat.*—Last season I secured some wheat for seed which contained a good sprinkling of smut. The variety was Currawa, one very subject to smut, in fact the greatest drawback the wheat has. I gave it a thorough pickling with copper carbonate. The weather at time of sowing was wet and showery, suitable condition for dry pickling. The crop at harvest time was almost free from smut. I have used the dry method of pickling wheat now for a number of years, and have found it very satisfactory. I always make a practice of using fresh pickle during the process of pickling, never using that which comes into the retainer, although the cost is a little more. *Wimmera Rye Grass.*—Another noteworthy feature during the year was the spread of this grass upon stubble land. The seed was sown with the previous wheat crop. Sheep readily ate the grass and did

well while grazing upon it. Anyone desirous of trying the grass should establish a broad leaf type. Another plant that is making its appearance—especially this last year—upon loamy soils is cluster clover. Stock relish it, and every effort and means should be adopted to encourage its growth and spread, for it will mean much to those who are engaged in grazing. *Fat Lambs.*—Three years ago a neighbor and I purchased a line of Merino ewes, taking half each; last season his were mated to Dorset Horn rams and mine to the Shropshire. Upon the same day, and to the same selling agents, we forwarded a consignment of 60 lambs each; in appearance three of his lambs would weigh four of mine dressed weight, yet mine valued 1s. more per head, the agents stating that mine were purchased by export buyers and his by local butchers. From this it plainly shows that as we have to rely on the export trade to get rid of our surplus of lambs, we shall have to study the requirements of the oversea purchaser in every way, not only in our lamb trade, but in our bacon and pork trade, and, in fact, everything we desire to export. In an endeavor to obtain fodder with as much nutriment as possible for use during autumn, I cut some Cape barley for hay very green, and so far all stock are cleaning it up, eating practically every straw. It is thrown out in the paddock for them to pick over. I have been particularly struck with the condition kept by two brood mares with foals at foot and supposed to be in foal again, their condition has been everything that can be desired. The mares have an abundance of milk for the foals. This hay is light and bulky, but if, on the other hand, it shows to be a good feed with more succulent nature than our other hays, it may pay to grow a little of it for autumn feeding personally. When it is cut care should be exercised in stooking, not stooking too soon and not building large round stooks, as it has a tendency to go fusty. Another point, in cutting tie the sheaves close to the butt, this will save a lot of trouble in handling. In the past year I have had considerable experience in keeping rabbits under control. The observation is simultaneous destruction of the pest is desirable, and all landholders should insist that this be done." A spirited discussion took place. Mr. A. Kelly thought barley hay for milking cows was too heating and gave the animals sore mouths. The writer replied, saying that probably the hay was cut too dry. Mr. M. Yelland said he often cut barley hay for feeding sows with litters. (Secretary, L. Yelland.)

March 24th.—Attendance, 27.

DEBATE.—The Milang Branch debated with Belvidere, to an excellent attendance of members and visitors, the subject being "Free Trade v. Protection." The visiting team being Messrs. I. Echett, M. Pearce, and S. Cheriton, and the local team Messrs. Beasley, A. Mattison, and L. Young. Belvidere supported free trade and Milang protection. After a spirited debate the adjudicator, Mr. Cochrane, announced that the Milang branch won by half a point, the results being 82½ to 82 points. (Secretary, L. Yelland.)

WOMEN'S BRANCHES.

THE FOOD VALUE OF MILK.

(Continued from Page 1195.)

THE PLACE OF MILK IN THE DIET.

Milk contains an abundance of protein, fat, carbo-hydrate, and inorganic salts. Its unique proteins are not only of superior value when used alone, but are also especially adapted to supplement the deficiencies of the proteins of the cereals that form so large a part of the daily ration of mankind. The scientific investigations of milk that have been made in the past three decades have all demonstrated that it plays an essential role in the human dietary, and is of particular benefit to the very young. Furthermore, they have also furnished an explanation of the esteem in which milk and its products have been held by the human race since the dawn of civilisation.

Nevertheless, it is necessary to point out that milk is not a perfect food, inasmuch as it does not, when used as the sole source of nutriment, supply adequate quantities of all of the factors required for the normal growth and well-being of animals. Although the consumption of liberal quantities of milk along with a dietary of other natural foods enhances physical development and health, its exclusive use over long periods of time has always led to nutritional disaster. This conclusion is the result of many futile attempts to rear and propagate calves, dogs, pigs, rabbits, and rats on milk diets under experimental conditions. Calves fed milk alone may grow fairly well for two to four months, but their weights then remain stationary; the animals become indifferent to food, and their joints become enlarged and stiff, with resultant interference with locomotion. Nervous disorders are also common symptoms. When rats are fed exclusively on whole milk, either fresh, boiled, autoclaved, or dried, their initial growth may be satisfactory, but later on they become retarded in growth, and reproduction does not occur. If the diet is continued sufficiently long, nutritional anaemia may result, depending on the availability of copper and iron in the cage and bedding.

The unfortunate "experiments" that have been unwittingly conducted on babies reared with the mistaken idea that milk is their perfect food should be mentioned in this connection. Malnutrition, loss of appetite, inability to sit erect and walk at the normal age, fretfulness, anaemia, and rickets are some of the untoward effects of a diet of milk alone over very long periods of time. The evidence is overwhelmingly convincing that milk is not a complete food for either man or animal, and should never be used as the *sole* food for any prolonged period of time, either for babies or for adults.

THE NATURE OF THE DIETARY DEFICIENCY OF MILK.

The addition of various food products, natural or purified, to milk dietaries may improve the diet in varying degrees, depending on the nature of the added food and the proportions in which it is administered. Bunge long ago showed that milk contained very little iron, but that young animals are able to grow for a time by virtue of a storage of this substance in their bodies at birth. Daniels found that soy beans, either as the meal or *meal ash*, were a satisfactory addition in promoting growth and reproduction in rats. Hart and co-workers were able to prevent or cure the characteristic milk anaemia in rats and other animals by introducing small amounts of copper, in addition to iron, into the ration.

McCollum and his associates conducted some interesting experiments with rats in an effort to find what foods could supply the substances in which milk is deficient. They fed diets that in most cases contained 60 per cent. of whole milk

powder, the rest consisting of dextrinized starch, together with one of the following foods:—Wheat and its various products, casein, gelatine, alfalfa, butter fat, cod liver oil, lard, egg yolk and albumin, hemoglobin, agar agar, beef liver, orange juice, and inorganic iron and copper salts. Of 38 diets used, only 24 allowed for production of young, and only 4 of these produced fifth generation young. Of the natural foods, liver appeared to be the most potent in supplementing the milk, but gave no better growth and reproduction than was secured by inorganic iron and copper together.

The conclusions reached by numerous investigators are that the outstanding deficiencies in milk are iron and copper, and that when these are supplied, although only very small amounts are needed, a milk diet will allow the animal body to function normally.

EFFECT OF HEAT ON THE NUTRITIVE VALUE OF MILK.

When milk is subjected to heat, certain changes take place which affect its physical character more than its nutritive value. A film forms on the surface of the milk boiled in an open utensil. Constant removal of this film will result in a diminution of both protein and inorganic salt content.

Alterations of the protein occurs to such an extent that when the heated milk is coagulated by rennin or by the acid of the gastric juice a softer and finer textured curd is obtained than with raw milk. Digestion and absorption of the protein are thereby facilitated. The lactalbumin of the whey undergoes partial denaturation, but is not damaged from a nutritive standpoint, by long continued heating such as accompanies the commercial evaporation of milk. Hence, persons who are unable to drink raw milk can often take evaporated milk without disagreeable results.

When milk is heated, a small amount of both calcium and phosphorus may be precipitated, but the nutritive value and ease of assimilation of the inorganic salts are probably not changed. The lactose and fat undergo no change, except that the latter, in evaporated milks, is broken up into much finer globules, which are more evenly distributed, more thoroughly emulsified, and hence are more readily acted upon by the digestive enzymes. A slight caramelization of the sugar may occur, thereby changing the taste slightly to resemble that of boiled milk.

The scurvy-preventing substance, vitamin C, is the only vitamin that undergoes rapid destruction upon being heated under ordinary conditions. Although boiling without stirring for a short period of time may not destroy it, commercial methods of concentration, evaporation, or drying leave little vitamin C in the final product.

During pasteurisation the only constituent of milk that suffers deterioration is vitamin C. This is of no great consequence, however, since its original content in milk is so far below the optimal for the child that additional vitamin C must be supplied from earliest infancy.

BIOLOGICAL EFFECTS OF DIETS THAT CONTAIN MILK

Other experiments have been reported which show remarkable growth and reproduction in rats, and give a scientific explanation for the wholesome effects observed in man when milk forms a liberal part of his diet. Perhaps the most widely discussed study is that conducted over a period of years by Sherman and Campbell. Two groups of rats, consisting of 1 male and 3 females each, were fed similar diets, the only difference being that 1 contained one-sixth whole milk powder and five-sixths whole wheat, whereas the other consisted of one-third milk powder and two-thirds of whole wheat. On the latter diet the rats grew faster, reproduced earlier, gave birth to more young, and reared a larger number of young rats. At the end of a year there were 361 descendants from this group, in contrast to 77 from the group that received the lesser proportion of milk powder. Furthermore, the animals that received more milk were of a somewhat larger size at all ages, and when maintained on the diet until natural death ensued, on the average lived distinctly longer than the others.

THE DAILY MILK REQUIREMENT.

A discussion of the nutritive value of milk would not be complete without consideration of the quantity required to make a dietary optimal. During infancy and childhood, because of the rapid increase in size of the skeleton, the need for inorganic salts is relatively enormous. Their assimilation and retention by the growing body is proportional to the amount eaten. In other words, large salt intakes induce the utilisation of especially large amounts of calcium and phosphorus. Sherman and Hawley have found in children that maximum retention of these constituents occurs when a minimum of 1 quart of cow's milk is consumed daily. This amount then has been taken as the standard required by a child to supply sufficient material for the normal growth of its skeleton.

Many pediatricians, however, believe that on account of the bulkiness of a quart of milk, and its low caloric value, it may be difficult for a child to eat enough other foods to obtain a well-balanced dietary. Loss of appetite, poor gastric motility, and anaemia are among the symptoms attributed to excessive milk drinking. Eliot, in the bulletin published by the Children's Bureau, "The Care of the Pre-School Child," advises that at least 1½ pints of milk be consumed daily.

If 1 quart of milk be given, careful selection of other foods must be made in order to supplement the deficiencies of milk. As brought out in this article, these deficiencies are calories, iron and copper, and the vitamins other than A. Additional roughage is also advisable. Generous amounts of fruits and vegetables, both raw and cooked, egg yolk, glandular meats, cod liver oil, and small amounts of whole cereal grains to supply calories make ideal additions to a diet built around 1 quart of milk per day.

THE COST AND ECONOMY OF MILK.

Most students of the science of nutrition are united in the belief that, under the economic and social conditions existing in this country, milk furnishes more of the substances essential in human food for the same amount of money than does any other single item of the dietary. Many technical reasons for this belief in the superior food value of milk have been given in the preceding sections; the present section deals with the extent to which milk can be considered as an economical food.

The economy of milk involves much more than a mere consideration of cost, for the question of the unique food value of milk must also enter into the discussion. The cost is significant only in terms of food value received for money expended.

THE PLACE OF MILK IN THE CHILD'S DIET.

In order to reduce the problem to practical terms, it is necessary to consider the economy of milk from the relationship of the monetary value of a given quantity of milk to its content of the dietary essentials, and also to show the contribution of this given quantity to the total daily food requirements of an individual. The daily food needs of a school-age child have therefore been chosen as the dietary standard to be met, and 1 quart the unit quantity of milk. These selections were made on the basis of the Sherman-Hawley experiments, which showed that optimum storage of calcium in children is attained when 1 quart of milk is consumed daily.

Although the number of units of vitamin A in many foodstuffs is known, the quantity required by the human body has not been definitely established. The experience of many investigators has indicated, however, that 1 quart of milk supplies the requirements of the child for vitamin A.

The quantities of protein and iron in milk are measurable, and the food fuel or energy value of 1 quart of milk is known. The child's need for protein was calculated on the basis of 12 per cent. of the 2,500 caloric standard, and the daily iron requirement was taken as 0.015 gram.

It is clear that a liberal proportion of the essential constituents of a child's diet is supplied by the consumption of 1 quart of milk daily, and that milk is a satisfactory basic food around which to build an adequate diet. The next point for consideration is, therefore, the correct selection of foods with which to supplement the quart of milk in making up the dietary. The cost of these foods, when compared with the price paid for milk, will reveal to what extent milk can be considered an economical food.

MILK AN ECONOMICAL FOOD.

Obviously, with less than half of the dietary essentials to be supplied, and, at the same time, with more than two-thirds of the calories still lacking, there is a wide range of foods from which to choose the remainder of the diet. Many combinations that insure an adequate diet have been devised, and for the purpose of the present discussion, one of the simplest is here presented. According to this, the daily diet of a child should contain the following foods, if the diet is to be complete:—*In addition to the quart of milk*, two or more kinds of fruit, of which one should be a citrus fruit or tomato; two or more vegetables, one preferably raw; one or more servings of whole grain cereal or bread; one or more servings of a high protein food, such as meat, fish, eggs or cheese; and enough additional food to fulfil the energy requirement. The problem in this case then is to select foods that yield about 1,800 calories which, when added to the 675 calories supplied by the quart of milk, furnish the 2,500 calories required by the child. An illustrative list of foods that might be selected is shown in Table IV.

By supplementing milk with these foods, not only the necessary energy is supplied, but the diet is rendered adequate in other respects as well. Ample quantities of vitamin C are contained in the raw fruits and vegetables, and iron is provided by the meat, fruits, green vegetables, egg, and whole grain cereal. The protein and phosphorus requirements are met by the meat, cereal, and egg, and a liberal excess of vitamin A is supplied by the butter, egg yolk, and green vegetables, thus providing for the much desired "health reserve" of this vitamin. The calcium requirement has already been met by the milk, and properly so in view of the probability that the calcium of milk is more completely utilised by children than is that from other sources.

TABLE IV.—*An Illustrative List of Foodstuffs that Might be Served Daily to Supplement 1 Quart of Milk for a Child 10 to 12 Years Old.*

Foods.	Calories.
1 orange	75
1 apple	100
1 serving prunes	100
1 serving coleslaw	50
1 serving peas	50
1 serving whole grain cereal	100
1 egg	70
1 serving meat	100
4 servings bread stuffs	400
1 ½ oz. butter	300
1 medium-sized potato	100
1 serving Brown Betty	200
2 small cookies	100
Sugar or other sweets	100

Total 1,845

Let us now examine the cost of these foods. When 1 quart of milk, which forms the foundation of the diet, costs 6d.*, this sum has satisfied the child's requirement

for calcium; has provided all, or practically all, of the vitamin A needed; has supplied nearly all of the phosphorus, two-fifths of the protein, more than one-fourth of the energy, and one-sixth of the iron. On the other hand, what must be paid for the foods that supplement the milk in completing the diet? Purchased at moderately priced markets, and at a time when staple food products are extremely low in price, this supplementary list of food costs approximately 1s. 3d.* This brings the cost of the meals for one day to about 1s. 9d.[•] There is, of course, a considerable variation in the price that has to be paid for these supplementary foods, and the selection of a wider variety of foods of choice quality adds materially to the total cost. But, bearing in mind the large nutritive contribution made by the quart of milk and the small fraction of the cost of the day's meals for which it may be procured, it is clear that milk may be regarded as a fundamental item of the child's diet, and, in the true sense of the word, as an economical food.

COST OF CALCIUM IN VARIOUS FOODS.

A still closer analysis of certain of the dietary factors of milk taken singly shows that many of these can be supplied at lower cost in milk than in any other way. One of the most striking examples of this arises from a consideration of the requirement of the human body for calcium. The question is frequently raised whether adults ordinarily obtain sufficient calcium from other foods than milk. Fruits and vegetables are generally regarded as good sources of calcium, and are often depended upon to take the place of milk in this respect. The question really involves two quite different considerations:—First, is it possible to supply the calcium needed by substituting fruits and vegetables for milk; and, second, if this is so, is the substitution economical from the point of view of cost?

For the present discussion the calcium requirement of the adult is taken at the generally accepted standard of 0.67 gram. daily. This amount of calcium would be supplied by the ingestion of slightly more than 1 pint of milk, which is the quantity usually recommended for the adult. In what quantities must fruits and vegetables be eaten if milk is to be supplanted by them as a source of calcium? For convenience, let us take the fresh fruits and vegetables from the supplementary food in Table IV.—oranges, apples, peas, and cabbage. The calcium content of these foods is as follows:—

Foods.	Measure.	Calcium (gm.)
Apple.	1	0.011
Orange	1	0.066
Peas	$\frac{1}{2}$ cup	0.014
Cabbage (shredded)	1 cup	0.036
Total		0.127

It is evident that, when served in the quantities designated, these fruits and vegetables do not meet the daily calcium requirement of the adult—an amount nearly fulfilled by 1 pint of milk. The second bar represents the contribution made by the calcium present in the quantities of fruits and vegetables proposed. Only one-fifth of the day's calcium requirement is met by the fruits and vegetables if these are eaten in the amounts stipulated. It is clear that, if they are to be depended upon as the sole source of calcium, it would be necessary to consume five times the suggested quantity in order to meet the calcium requirement. In other words, it would require 5 oranges, 5 apples, 5 servings of peas, and 5 cups of cabbage to furnish the amount of calcium needed each day. Aside from the practical difficulty of consuming such quantities of these foods, there is the more pertinent question of cost.

To obtain the calcium needed for the day in milk may cost 3d.* To obtain the same amount of calcium in the form of oranges, apples, peas and cabbage the cost would be, at the lowest, 1s. 10½d.* But the reader may point out that it is not the primary function of fruits and vegetables to furnish calcium. It is true that these foods serve other useful purposes, and their value to the body should not be discounted on the basis of this discussion. The fact remains, however, that the person who buys adequate amounts of calcium in the form of fruits and vegetables instead of milk must eat far greater quantities of these than are required to fulfill their other functions in the body. Obviously, such a procedure would not be defensible if economy were the main consideration.

Although it is evidently impracticable to maintain the calcium intake at a proper level by depending alone on fruit and vegetables, one may still feel that the other foods in the diet, exclusive of milk, fruits and vegetables, may meet this requirement. That this is not the case may be shown by referring once more to the supplementary food list. The calcium content of the foods in this list is fairly representative, but the quantities recommended are those to be used in supplementing the daily quart of milk in the diet of a child. The energy value is approximately 1,800 calories, whereas an adult at a sedentary occupation requires approximately 2,800 calories. It is necessary therefore to increase the suggested quantities by approximately 50 per cent. Table V. gives the calcium content of the item of food in the supplementary food list. The total calcium that can be derived from this diet is about 0.3 grams. If this is increased by 50 per cent. in order to make up the amount of energy necessary for the adult, the intake of calcium would be 0.45 grams. It is clear, therefore, that this diet is markedly deficient in calcium. The substitution of cheese for a part of the protein would, however, do much toward correcting this deficiency, since cheese contains relatively more calcium than any of the other foods mentioned.

TABLE V.—*The Calcium Supplied by the Items of the Supplementary Diet Shown in Table IV.*

Foods.	Calcium (gm.)
Prunes	0.018
Rolled oats	0.017
Egg	0.032
Meat	0.008
Bread stuffs (4 servings)	0.076
Potato (1 serving)	0.017
	<hr/>
	0.168
Orange, apple, peas, and cabbage	0.127
	<hr/>
Total	0.295

The necessary quantities of these foods may be bought for from 9d.* to 1s. 0½d.* Again the economy of milk is evident. One pint supplies practically the whole of the adult's daily need of calcium for about 3d.* The other foods in the diet supply from one-half to two-thirds of the quantity needed at more than three times the cost.

Although a child's need for calcium is satisfied by 1 quart of milk, the equivalent in calcium is not only difficult to obtain on other foods, but is much more costly in comparison with the milk.

MILK IN THE LOW COST FOOD BUDGET.

In the making of food budgets, milk and its products have always been accorded a place. One widely used guide for the division of the food fund in the "one-fifth" plan first suggested by Gillett. This plan recommends spending one-fifth of the food

budget for milk and cheese, and approximately one-fifth for each of the other four main groups of foodstuffs. It should be noted particularly that this division is suggested for a family living at a fairly comfortable level of expenditure for foods. The extent to which Gillett regards milk as an economical food is revealed by her recommendations when the food fund is reduced below the comfort level. She has found from experience that, when there is less money to spend, it is necessary to use nearer one-third of the food money for milk and cheese in order to provide adequately for the needs of the family. As the total amount of money spent for food is decreased, care must be exercised to see that the quantity of milk used is not lessened.

In direct line with the above suggestions regarding the distribution of the food fund are the specific recommendations made by Sherman as to the purchase of foods when the diet must be reduced to its cheapest level. He says, in brief:—"The diet should be built around bread and milk. The lower the level of expenditure, the more one must forego other foods, and concentrate effort upon providing these two, supplemented by a little of some inexpensive fruit or vegetable." He follows this with the statement:—"Milk builds bone and muscle better than any other food, and, more than this, milk is both the cheapest and surest protection from nutritional deficiencies. . . ."

Gillett and Rice have recently shown, by a study of the budgets of city families, that those families which spent a larger proportion of their food fund for milk and cheese actually bought their total food supply more economically. The study involved a detailed investigation of the diets of city families on low incomes. One hundred of the families were "uninfluenced" in the buying of their food; an additional 20 families were "influenced" by investigators, who gave specific instructions in food values. The findings of the study made in 1928 were compared with the findings of a similar study made on approximately the same number of families and under similar conditions in 1914.

It is interesting to see the extent to which the investigators were successful in influencing families in the distribution of their food money with respect to the purchase of milk. (A graph published in the original bulletin shows the percentage of the food fund actually spent for milk and cheese by the four groups of families studied.) From this it is evident that there was a definite although small increase in the proportion spent for milk and cheese from 1914 to 1928. This was probably the result of the general dissemination of knowledge of food values over a period of years among the "uninfluenced" group. The pronounced and significant difference between the "uninfluenced" group and those under the tutelage of the trained advisors of both years, 1914 and 1928, is striking. The 1928 study was prompted by the desire to obtain information to guide in making revision, if such were necessary, of the suggestions on food expenditure for low-income families. Whether or not such change in the distribution of the food budget is significant rests entirely upon the effect on the cost and quality of the family diets. Is there, for instance, an advantage in so shifting the distribution of the food fund that more money is spent for milk? And, if so, is this advantage so pronounced that low-income groups ought to be urged to adopt this plan for their own food expenditure? The findings of the study appear sufficiently conclusive to answer the questions in the affirmative. The survey of family dietaries showed that, as the distribution of the food fund approached that recommended, it was possible to purchase diets of higher food value at less cost.

[*In the original Bulletin the money values referred to were quoted in cents. For the convenience of local readers, these have been converted to Australian coinage on the basis of 1 cent. equal to $\frac{1}{2}$ d.—Editor.]

POTATOES—50 WAYS FOR 50 DAYS

[By A. L. MARLATT.]

(Special Circular Issued by the University of Wisconsin, U.S.A.)

Thrifty housewives know that a "big potato crop" means a cut in the family food bill. When potatoes are plentiful they may be used widely, from soups to desserts, for their mild flavor does not become tiresome, and they are wholesome and easy to prepare.

The potato contains valuable proteins, minerals and vitamins, in addition to its starch, so that it need not be forbidden food for persons on a reducing diet, providing it is properly balanced with milk, meat, fish or eggs.

In comparing the value of the potato with such cereal foods as wheat, oatmeal and corn, scientists have found it has a better muscle repairing content; it is very high in alkaline salts, which are needed to offset the acid salts of meats; it is fair in iron; low in Vitamin A (as are the cereals), fair in vitamin B, but high in vitamin C; and that it contains one of the easiest starches to digest. Vitamin A, it will be remembered, is very important, as it gives increased resistance to infections. Vitamin B determines the quality of the appetite, and prevents poor nutrition conditions. Vitamin C, in which the potato is rich, prevents scurvy.

While the iron in potatoes is not high, yet if they are eaten in liberal quantities the iron becomes of value. The potato is also low in lime salt, but this is easily supplied by using plenty of milk when serving potatoes.

The high vitamin C value of the potato has been known for many years. In the famines in Ireland, when potatoes were the only food, there was no scurvy, and also in the days of sailing vessels it was commonly known that when ships had a plentiful supply of potatoes the sailors never suffered from scurvy. In Poland and Russia, where the potato is very important in the diet of the rural people, such diseases as pellagra and scurvy are practically unknown.

In America, where potatoes are used as a supplementary food to balance the proteins of milk, meat and eggs, the values of vitamins A, B, and C are adequate for all but very young children. For them, vitamin A must be enhanced by the use of butterfat, and for infants by the use of cod liver oil or sunshine as a protection against rickets.

POTATO BUILDS MUSCLE.

In several studies made with adults who were fed a uniform diet, including potatoes, to the extent of 2lbs. to 2½lbs. a day, the body weight stayed nearly constant, the digestion was excellent, and the people did not tire of the diet. These studies indicated that the potato is able to sustain the body in a state of nitrogen balance, so that even in muscle building this vegetable is a distinct aid in the diet when costs must be considered. In comparing the value of the potato with wheat bread, 1 3oz. potato (320 potatoes to the bushel) is equal to 2 slices of white bread, or 10 medium-sized potatoes will equal 1 lb. loaf of bread, or 1bush. of potatoes will equal in all ways 32 lb. loaves of wheat flour bread.

FOOD VALUE HIGH.

The main calorie or heat-producing value of the potato is in its starch, which has been known as one of the most satisfactory of starches for human food. It is of interest to know that in human feeding where the potato is used as one of the main foods, even up to 2lbs. or 3lbs. in the diet, steaming seemed to be the method that was found most satisfactory for the long period; but the potato lends itself to all methods of cooking. The problem is to reduce the quantity of mineral loss by safeguarding the methods.

LOSS OF MINERALS IN COOKING.

Studies in our agricultural laboratories at the University of Wisconsin have shown that steaming, baking, or cooking without water in the waterless cooker are all better than boiling the potato in the skins, or boiling it after peeling. In the latter case the percentage of loss in both mineral matter and protein may be very high. Recent work from these same laboratories indicates that loss of manganese, one of the minerals found in the potato, may, through pressure cooking or boiling in a moderate amount of water, be as high as 9 per cent. As manganese is now known to be an important element along with calcium, phosphorus, magnesium, iron, chlorine and iodine, the method of preparation in cooking the potato becomes important.

METHODS OF COOKING.

In careless preparation and cooking of the potato, as high as 30 per cent. of its food value may be wasted. This loss is greatest in the muscle-building material (protein), and in the mineral matter. For example:—

1. Peeling and slicing the potato, allowing it to stand a long time in water before cooking, will waste the protein and mineral matter.

2. Placing the peeled potato, without previous soaking, in cold water and bringing the water quickly to the boiling point will waste the protein and the mineral matter.

3. Placing the peeled potato at once in salted boiling water and boiling the water rapidly will waste less of its protein and mineral matter.

4. Baking or steaming the potato with the skin on wastes none of the protein or the mineral matter.

If roughage is needed in the diet, the baked potato should be eaten with the skins on.

5. Cooking the unpeeled potato without water in a heavy covered vessel over the direct heat destroys none of the protein or the mineral matter.

The rule should be to boil or steam the potato and remove the skin after it is cooked. Then the potato may be cut into the form appropriate to any one of the fifty or more ways in which it can be served.

If peeled and cooked in boiling water, the water in which it is cooked should be used with the potato, or saved to be used in making soup or in making bread, because the water in which the potato is boiled may contain 30 per cent. of the protein and 30 per cent. of the mineral matter. The most wasteful method of preparation and cooking may mean a loss of over half the protein and over a third of the mineral matter.

BAKED POTATOES.

1. Bake potatoes of medium size and smooth skin; 30 to 40 minutes should make them mealy.

2. Boil large potatoes for 5 minutes, and then bake for 40 minutes in a hot oven.

3. Rub the skin of potato with sweet fat, and then bake slowly in a moderate oven 50 to 60 minutes. This will keep the skin tender and edible.

4. Baked potatoes must be broken open as soon as tender. Too much cooking will, because of the confined steam, make the starch sticky and the potato soggy.

5. When potatoes are baked and the family is not ready for them, the potatoes may be cut in halves and the mealy centres removed, beaten smooth with cream or fat, returned to the shells, and kept warm in the oven.

BOILED POTATOES.

1. Place washed but unpeeled potatoes in boiling salted water (1 teaspoon salt to 1 quart water). Boil potatoes from 20 to 30 minutes, or until easily pierced with a fork. Drain the water. Heat the potatoes in a dry vessel until all water

from surface of potato is evaporated. Remove the skins, and prepare according to any rule calling for cooked potatoes.

STEAMED POTATOES.

1. Steam the potatoes without peeling. The steaming process must be continuous and rapid for about 30 minutes. When the potatoes are tender they should be removed from steam and dried in a hot oven. They are then ready for further preparation before serving, or they may be served in their jackets.

FLAVORINGS.

Because the potato is mild in flavor it lends itself to varied uses with other foods in preparation of dishes.

1. *Salt*: Because of its potash salts we demand instinctively the use of common salt in the cooking of the potato. This instinct is founded on a vital need, as the two salts balance each other in the normal human body.

2. *Pepper*: Black, sweet red (paprika), or cayenne may be used in all potato dishes.

3. *Onion* is always an excellent flavor for potato served as chowder, soup, creamed, or in form of bean or meat loaf.

4. *Garlic*, raw, may be chopped and used in potato salad, or the sections or cloves of garlic peeled and sliced may be cooked with the potato dishes in which tomato, onion, or meat form a part. The cooked garlic has a mild flavor quite different from the onion flavor.

5. *Herbs*: Thyme marjoram, bay leaf, summer savory, may be put into the water in which the potato is boiled, thus varying the flavor, but the amount used should be very small. Such variations in flavor should be used rarely. Mint leaves may be used in the water in which new potatoes are cooked.

6. *Curry Powder*: Curry powder, which is so commonly used in East Indian cookery, may be used in preparation of potato curries, in which potato takes the place of rice. Curry should be used only when the cook knows the family is fond of it.

The potato is native to the region including Peru, Ecuador, Bolivia, and North Chili. Along the arid desert which forms the Pacific coast of this region there is a succession of cemeteries in which mummies are found, accompanied not only by dried plants, but also by funeral vases of terra cotta, on some of which are pictured food staples and fruits of the ancient inhabitants. Dried potatoes have been found in these graves, and funeral vases picturing potatoes are abundant.

The potato was introduced into Europe in the latter part of the 16th century, although there is some question as to how this was done. In American agriculture the potato was unknown until the early part of the 18th century. In all countries, however, there was strong opposition to the introduction of this new vegetable. Some protested on account of its presumed harmful effect on the mind, and others because it was not mentioned in the Bible. The cultivation of the potato in France was first brought about by Parmentier; and in 1785 at a fete the king used the flowers of the potato as a buttonhole bouquet, and Marie Antoinette wore them in her hair.

BREAKFAST.

The preparation of breakfast should consume as little time as possible. Therefore use potato recipes which will call for potato which has been cooked, as hashed brown potato.

Boiled Potato with Gravy (serves 6).—Steam or boil the potato in its jacket until tender (20 to 30 min.); peel and serve unmashed with butter or with cream sauce or creamed dried fish or creamed dried beef.

Cream Sauce.—2 level tablespoons fat, 4 level tablespoons flour, 2 cups milk, 1 teaspoon salt, $\frac{1}{2}$ teaspoon pepper. Melt the fat, add the flour, and stir until a smooth mixture. Add all the milk, and place in the dish in another dish containing boiling water (double boiler), and cook until the mixture is smooth and thick like cream, stirring constantly. Add the seasoning.* (Any sweet clarified fat from beef, chicken, or pork may be used, or any of the butter substitutes may be used in place of butter.) One-fourth teaspoon of soup coloring will improve the color and flavor of the sauce.

Variations may be made by adding to the completed sauce 1 cup of finely divided salt fish, which has been allowed to soak in water over night and the water drained in the morning, or the same amount of finely divided dried beef may be soaked over night, drained, and added to the sauce. In both cases the sauce should be reheated thoroughly before serving.

Any left-over meat may be cut into $\frac{1}{2}$ in. cubes and added to the white sauce in the proportions of $\frac{1}{2}$ cup of meat to 2 cups of the sauce.

Potato Hash (serves 4-6).—Equal parts of finely chopped cooked potato and chopped cold cooked fish or meat may be used as a basis for a breakfast dish. 2 cups chopped potato, 2 cups chopped meat, 1 teaspoon salt, $\frac{1}{2}$ teaspoon pepper, 3 tablespoons fat, $\frac{1}{2}$ cup boiling water. Melt the fat in the frying pan; add the potato and meat mixture, pour over the top the water, and cook slowly without stirring until the under surface is a rich brown. Fold as an omelet and serve hot on a platter.

Omelet (serves 4).—1 cup mashed potato, $\frac{1}{2}$ teaspoon of pepper, 1 teaspoon salt, 3 eggs, 3 tablespoons cream or milk. Wash eggs and separate the whites and yolks. Add the yolks to the potato and beat until there are no lumps. Season with onion juice, if desired, and chopped parsley. Beat the whites until stiff, and fold into the potato mixture. Put into a well-oiled frying pan, and bake in oven until brown. Then turn and fold on hot platter. Serve at once.

LUNCHEON OR SUPPER.

The potato may be the principal ingredient in soups, chowders, or purees, the main vegetable served with hot breads and cheese dishes, or a part of a meat substitute dish, such as croquettes or a loaf. It may appear in the salad, in the hot breads, or in the dessert.

SOUPS.

Cream or Potato Soup (serves 4-6).—1 quart milk, $1\frac{1}{2}$ cups cold mashed potato or 3 medium potatoes boiled in their skins, peeled, and mashed, 2 tablespoons fat, $1\frac{1}{2}$ tablespoons flour, 1 tablespoon chopped onion or onion sprouts, 1 tablespoon chopped parsley (may be omitted), $1\frac{1}{2}$ teaspoons salt, $\frac{1}{2}$ teaspoon white pepper, or $\frac{1}{2}$ teaspoon red pepper, $\frac{1}{2}$ bay leaf (may be omitted). Heat the milk in a double boiler with onion and the bay leaf. These should be removed before the milk is used. Melt the fat, add the flour, mix until smooth; add the milk, return to the double boiler and cook, with stirring, until the mixture is smooth. Add the salt, pepper, and the mashed potato, beating until smooth. Heat thoroughly, and sprinkle in the chopped parsley just before serving.

Fish Chowder (serves 4-6).— $\frac{1}{2}$ lb. pound salt fish, 3 cups potato cut in small pieces, 4 cups milk, 2 ozs. salt pork, 1 small onion (chopped), $\frac{1}{2}$ teaspoon pepper, 2 tablespoons flour. The fish may be cod fish, smoked halibut, or any other dried fish. The fish should be free from bone and cut into small pieces. If very salt, it should soak in water over night. The salt pork should be cut into small pieces and cooked with the chopped onion until the onion is a golden brown. Add the

*All measures are level. Do not pack or press into the cup or spoon, but lightly fill the measure.

potato, and cook for 10 minutes. Add the milk and fish, and cook slowly in a double boiler or over a water bath until the potatoes are tender. Add the flour mixed to a smooth paste with an equal amount of cold water. Add the pepper and additional salt, if necessary. Cook until the mixture is creamy.

Corn and Potato Chowder.—In the above recipe substitute 1 pint of canned corn for the fish.

Potato and Tomato Chowder.—In the fish chowder recipe in place of 1 cup milk, use 1 cup of canned tomato pulp added after the flour has been thoroughly cooked in the chowder. Serve as soon as possible, else the tomato may curdle the milk.

VEGETABLES.

Scalloped Potatoes.—Cut the potatoes in slices $\frac{1}{2}$ in. thick. Place the potatoes in layers in a greased dish. Pour thin white sauce over them. Bake in a slow oven one hour, and, when half done, sprinkle with oiled crumbs.

Potato and Curry (serves 6).—4 cups potato, cut in dice, $\frac{1}{2}$ cup onion chopped fine, 1 cup boiling water (in which potato has been cooked), 4 tablespoons oil (corn), 1 teaspoon curry powder, 2 teaspoons salt, $\frac{1}{2}$ cup grated cheese. Peel and cut the raw potatoes into $\frac{1}{2}$ in. dice, boil until they are tender in just enough water to cover. Cook the chopped onion in the oil until the onion is golden brown. Add the potato and a half cup of boiling water to the onion. The water should just cover the potato. Additional boiling water should be added as needed. When the potato is tender (15 minutes) add the curry powder, which has been mixed with an equal quantity of cold water. Mix gently, and pour the potato mixture into the serving dish, sprinkle with the grated cheese, and serve at once.

Armenian Potatoes (serves 6).— $\frac{1}{4}$ cup oil, 1 quart of raw diced potato, $\frac{1}{2}$ cup tomato pulp, $\frac{1}{2}$ cup water, 1 $\frac{1}{2}$ teaspoons salt, 1 teaspoon paprika or white pepper, 1 garlic separated into cloves, and each clove peeled and sliced, 1 bunch parsley, or 1 tablespoon dried parsley. Mix in the order given, and bake in a covered dish in a slow oven 40 minutes.

POTATOES USED AS MAIN DISH.

Potato O'Brien (serves 4).—2 cups diced cooked potato, 1 tablespoon flour, 1 tablespoon fat, $\frac{1}{2}$ cup skimmed milk, 1 teaspoon salt, $\frac{1}{2}$ teaspoon pepper, 1 green pepper cooked and chopped, $\frac{1}{2}$ cup grated American cheese, $\frac{1}{2}$ cup bread crumbs. Make the sauce, using the fat, flour, milk and seasoning. Mix the potato and the green pepper with the white sauce and cheese. Put in a baking dish, and cover with the bread crumbs and brown in a hot oven. Note.—Canned red peppers can be used in place of green pepper.

Pittsburg Potatoes (serves 4).—1 quart potato cut in cubes, $\frac{1}{2}$ lb. milk cheese, $\frac{1}{2}$ can pimientos, 1 onion, 2 cups white sauce, $\frac{1}{2}$ teaspoon salt. Cook potato cubes and onions finely chopped in boiling salted water 5 minutes. Add pimientos cut in small pieces, and cook 7 minutes; then drain. Turn into oiled baking dish, and pour over white sauce mixed with cheese and salt. Bake in moderate oven until potatoes are soft.

Cheese and Potato (English) (serves 4).—3 cups raw potato sliced thin, 3 ozs. fat, 4 ozs. grated cheese, 2 cloves garlic chopped fine, 2 teaspoons salt, $\frac{1}{2}$ teaspoon pepper. Arrange in baking dish, using alternative layers of potato, cheese, fat, and seasoning. Cover tightly, and bake in moderate oven until the potatoes are tender (1 hour). Decorate with chopped parsley, and serve in the baking dish. (Note.—The use of garlic gives the cheese a flavor resembling parmesan.)

Juliennes Potato with Savory Sauce (serves 4).—3 cups potato cut in strings, 2 teaspoons mixed herbs, 2 ozs. fat, 2 small onions (chopped), 2 tablespoons flour, 1 pint milk, 2 teaspoons salt, $\frac{1}{2}$ teaspoon pepper. Cut the raw peeled potatoes into strings the size of macaroni. Cook them in boiling salted water 20 minutes.

Brown the chopped onion and the herbs in the fat. Add the flour, stirring thoroughly; add the milk, salt and pepper, and cook in a double boiler 20 minutes. Strain and pour over the cooked potato. Sprinkle with grated cheese and serve.

Potato and Lima Bean Loaf (serves 4-6).—1½ cups cooked lima bean (sieved), 2 tablespoons fat, ½ cup milk, 1 teaspoon salt, ½ teaspoon sage, 2 cups riced potato, ½ cup milk, ½ teaspoon fat, ½ teaspoon fat for brushing. Mix first five ingredients, and place in bottom of an oiled dish. Whip together the hot potato and the remaining ingredients. Place this mixture on top. Bake in quick oven. Serve with tomato sauce.

Potato and Bean Cutlets (serves 4).—1 cup riced potato, 1 cup riced lima beans, 1 can pimientos, ½ cup bread crumbs. Mix thoroughly, and salt to taste. Form into shapes to look like cutlets. Dip into beaten egg, and sprinkle with bread crumbs, and bake in a moderate oven until slightly brown. Turn carefully, and brown on the other side. Serve with a tomato or cheese sauce.

Cheese Sauce.—2 tablespoons fat, 2 tablespoons flour, 1½ cups milk, 1 cup grated cheese. Brown the flour in the melted fat, add the milk, and cook for 5 minutes, and add the cheese. Remove from the fire, and stir until the cheese is melted.

Potato Puffs (serves 4-6).—2 cups mashed potato, 2 eggs, ½ cup milk, 1 teaspoon salt, 1 cup grated cheese. Add the milk to the potato and beat until thoroughly blended. Add the beaten egg and salt, gradually adding the grated cheese. Bake in buttered tins or ramekins in a slow oven.

Stuffed Potatoes.—Select medium-sized, smooth-skinned oval potatoes. Bake in a hot oven until tender, being careful not to over-brown the skin. Cut the potatoes in two lengthwise; remove the potato pulp, being careful to leave shells unbroken. Mash the hot potato; add either milk or cream as for mashed potato. Season as follows:—To each cup of potato add ½ saltspoon salt and ½ saltspoon of pepper. Fill the shells with this mixture, rounding the surface so that it is the shape of the original potato. Bake for 10 minutes in a hot oven.

Variations.—Fold into the two cups of seasoned potato pulp the beaten white of an egg; pile lightly in the potato shells, and bake. Grated cheese ½ cupful to 2 cups of potato pulp may be used.

Surprise Potatoes.—Bake the potatoes as in the preceding recipe. Cut one end, hollow out the centre of the potato; place in each potato one egg which has previously been poached; cover with mashed potato, stand potato in the oven for 5 minutes, and serve.

American Kedgerie (serves 6).—1 pint diced potato (cooked), 1 pint kidney beans (cooked), 2 hard boiled eggs, 1 medium sized onion, 2 teaspoons curry powder, 1 teaspoon lemon juice or vinegar, 2 teaspoons salt, ½ teaspoon pepper, 2ozs. fat or oil. Chop the onion fine, brown in fat, add curry powder and lemon juice; cook 5 minutes; add the potato, beans, chopped white of the eggs. Heat in stew pan or baking dish. Serve with top covered with the yolk of eggs passed through sieve.

Vegetable Curry (East Indian) (serves 6).—2ozs. diced carrot, 2ozs. diced turnip, 2ozs. diced potato, 2ozs. cooked peas, 2ozs. cooked beans (navy, kidney, or haricot), 2 hard boiled eggs (sliced), 4 peeled bananas (sliced), 1 peeled apple (diced), 2ozs. oil or butter substitute, ½ pint water, ½ pint milk, 1 level tablespoon turmeric, 1 level tablespoon curry powder, 1 tablespoon flour (corn or rice). Brown the diced vegetables in the fat; add the fruit, the curry powder, turmeric and flour; mix thoroughly; add the water; then simmer for ½ hour. Add the milk and hard boiled eggs. Heat and serve with a border of boiled rice.

Quick Oven Browned Potatoes.—Cut potatoes in 1-inch slices. Place in an oiled baking pan; cover with fat, and bake in a moderate oven. Bacon drippings are especially good to use for the fat.

Meat Loaf (serves 4-6).—1lb. ground beef, $\frac{3}{4}$ lb. ground pork, $\frac{1}{2}$ cup mashed potatoes, $\frac{1}{4}$ cup milk, 1 teaspoon salt, $\frac{1}{4}$ teaspoon pepper, $\frac{1}{2}$ teaspoon minced onion, if desired. Mix all ingredients together, and form into a loaf. Bake in a hot oven from 45 minutes to 1 hour. Potato takes the place of egg as a binder.

SALADS.

Potato Salad (serves 4-6).—6 hot boiled potatoes, 1 tablespoon finely chopped onion, 2 tablespoons finely chopped parsley. Cut the potatoes into $\frac{1}{2}$ in. cubes, mix hot with the onion and the parsley, and add any salad dressing, French, boiled, or cheese. Mix thoroughly and chill. Using the potato hot allows the dressing to penetrate much more thoroughly, so that the flavor is uniform throughout.

Variations.—To the above any one of the following may be added:—1 cup chopped celery, 1 cup diced carrots, 1 cup peas, 1 cup diced cucumbers, 2 hard boiled eggs, the whites diced and the yolks rubbed through a sieve.

Salad Loaf.—Place a layer of potato salad in a glass dish, cover with layer of meat salad. Alternate until dish is full, pressing into firm layers. Chill and unmold on platter. Decorate with mayonnaise dressing and red pimento, and serve on lettuce leaf.

Macedoine Salad (serves 6).—1 cup diced potato (cooked), $\frac{1}{2}$ cup diced carrot (cooked), $\frac{1}{2}$ cup cooked peas, $\frac{1}{2}$ cup shredded cooked string beans, $\frac{1}{2}$ cup cooked diced beet. Mix with $\frac{1}{2}$ cup of French dressing or boiled dressing. Garnish with parsley or shredded cabbage.

Southern French Dressing.— $\frac{3}{4}$ cup oil, $\frac{1}{4}$ cup vinegar, juice of $\frac{1}{2}$ lemon, 1 teaspoon salt, 1 teaspoon sugar, 1 teaspoon mustard, $\frac{1}{2}$ teaspoon paprika or white pepper, 1 clove garlic (sliced). Pour into bottle, and shake thoroughly before using. This will keep in a cool place for an indefinite time, and is always ready.

Cheese Salad Dressing.—1 cup milk, 1 tablespoon flour, 1 tablespoon fat, $\frac{1}{4}$ cup vinegar (mild), $\frac{1}{2}$ cup grated cheese, $\frac{1}{4}$ teaspoon paprika or white pepper, $\frac{1}{2}$ teaspoon salt, 1 tablespoon onion juice (optional). Add flour to warm fat. Add milk, and cook as for white sauce; add vinegar and warm. Then add seasoning and cheese.

DINNER.

Potato cooked in some form has become the accepted accompaniment of the meats served at dinner. It may be served with the meat as the main source of starch to balance the protein of the meat as baked potato, potato puffs, mashed potato, potato croquettes, or as creamed potato. It may be reserved to serve as a side dish in the form of a potato salad, or it may be served as part of that popular dish, a New England dinner, corn beef and cabbage.

Mashed Potato.—Select medium-sized potatoes; scrub thoroughly, and cook in boiling water, or steam until tender. Peel, add 1 tablespoon hot milk or cream or fat, and 1 saltspoon of salt, and $\frac{1}{2}$ saltspoon of pepper to each cup of potato. Beat the mixture with a fork until light and white. Pile in a hot serving dish.

Variations.—Mash the potato with the seasoning, and put it through a potato ricer, letting it fall into a baking dish, so that it piles lightly. Brown the surface in a very hot oven or under the broiling flame.

Baked Potato.—See preceding rules.

Note.—The baked potato must never be allowed to wait without being broken open as soon as it is cooked. Even then it quickly loses its mealiness on standing. Therefore, the potato should be put into the oven at a time when it will be done at the moment when it should be served. In case of delay, following any of the rules for stuffed potato will prevent the potato from becoming soggy before serving.

Potato and Celery Hash (serves 4).—6 medium sized boiled potatoes, 1 cup cut celery, 1 teaspoon salt, 3 tablespoons fat. Mix the cold potatoes with finely cut celery. Add the salt and the melted fat, stir together, place in a hot oven, and bake until well browned on top. Stir the potatoes, and let brown again. Repeat this two or three times until the potatoes have browned throughout and the celery is well cooked.

Raw diced potatoes may be cooked with the celery in boiling salted water for 20 minutes. When tender reduce water by rapid boiling; add the fat, pour into baking pan, and cook 10 minutes in the oven.

Potato Balls (serves 4).—3 cups mashed potato, 1 teaspoon salt, $\frac{1}{2}$ teaspoon white pepper, 1 egg beaten slightly. Beat the potato, salt, pepper, and $\frac{1}{2}$ of the egg together. Measure in tablespoons; dip each in flour, and roll either in the form of balls or in cylinders; place in an oiled baking dish, brush the surface of each ball with the remainder of the egg mixed with an equal amount of milk. Brown in a hot oven 20 minutes.

Potato Souffle (serves 4-6).—4 cups hot mashed potato, 1 tablespoon melted fat, 2 tablespoons milk, 1 teaspoon salt, $\frac{1}{2}$ teaspoon pepper, yolks of 2 eggs, whites of 2 eggs beaten stiff. Mix all but the whites of the eggs in the order given; beat thoroughly, fold in the stiffly beaten whites, pile in a baking dish, and cook until the mixture puffs and is brown on the top.

Franconia Potatoes.—Select small (2oz. or 3oz.) potatoes. Peel; place around the roast in the baking dish 30 to 45 minutes before the meat will be cooked. The potatoes should be golden brown in color and tender when served.

Potato Peanut Loaf (serves 4-6).—1 pint mashed potatoes, 1 cup ground peanuts or $\frac{1}{2}$ cup peanut butter, 2 teaspoons salt, $\frac{1}{2}$ teaspoon pepper, $\frac{1}{2}$ cup milk, 2 tablespoons fat, 2 eggs. Beat the entire mixture together, and place in greased baking dish; set in a second pan containing hot water, and bake in the oven until firm. Serve with tomato sauce.

Potato Fish Loaf.—The same as above, except in place of ground peanuts use chopped cooked fish.

Shepherd's Pie (serves 4-6).—2 cups cooked flaked fish, 1 cup soup broth (beef), 1 tablespoon fat, 1 tablespoon flour, $\frac{1}{2}$ teaspoon salt, $\frac{1}{2}$ teaspoon pepper, 2 cups mashed potato. Put diced or flaked fish in baking dish. Add sauce made of the fat, flour, seasoning and broth. Cover top with mashed potato, brush with fat or cream, and brown in a hot oven.

DESSERTS.

Potato and Carrot Pudding (serves 6).— $\frac{1}{2}$ cup fat, 1 cup grated raw carrot, 1 cup grated raw potato, 1 cup brown sugar, $1\frac{1}{2}$ cups seeded raisins, 1 cup nuts, 2 eggs, 3 teaspoons baking powder, $\frac{1}{2}$ teaspoon cinnamon, $\frac{1}{2}$ teaspoon cloves, $\frac{1}{2}$ teaspoon nutmeg, 1 teaspoon salt, $1\frac{1}{2}$ cups flour. Cream butter, add sugar, beat; add eggs, beat. Add vegetables. Mix and sift baking powder and seasoning with flour, and beat; then add fruit dredged with small part of the flour. Steam 3 hours.

Lemon Potato Pie (serves 4-6).—1 3oz. potato, 1 cup sugar, grated rind of lemon, juice of 1 lemon, 1 cup boiling water, yolks of 2 eggs, whites of 2 eggs, 2 tablespoons powdered sugar. Peel and grate the potato into the water. Cook 5 minutes, stirring constantly. Add the sugar, grated rind, yolk of egg; cook until the mixture thickens, stirring constantly. Add the juice of the lemon and pour the mixture into the baked crust. Beat the whites of the eggs stiff, fold in the powdered sugar, spread over the filling so that the meringue touches the crust, but is rough over the entire surface. Bake in a moderate oven until a delicate brown.

Chocolate Potato Cake (serves 6).— $\frac{3}{4}$ cup mashed potato, $\frac{1}{2}$ cup fat, 1 cup sugar, 2 eggs, slightly beaten, $\frac{1}{2}$ cup grated chocolate, 1 cup flour, 1 teaspoon baking powder, $\frac{1}{2}$ teaspoon salt, $\frac{3}{4}$ cup milk. Cream fat and sugar. Add eggs and potato. Add the flour, mixed with the baking powder and salt, alternately with the milk. Add the chocolate last. Bake in layers or muffin tins.

Chocolate and Nut Potato Cake (serves 6).— $1\frac{1}{4}$ cups sugar, 1 cup lard or butter, 1 cup cooked potato, $\frac{1}{2}$ cup milk, 2 cups flour, 4 eggs beaten lightly, $\frac{1}{2}$ cup chocolate (melted), $\frac{1}{2}$ cup chopped nuts, $\frac{1}{2}$ teaspoon cloves, $\frac{1}{2}$ teaspoon cinnamon, 2 teaspoons baking powder. Cream sugar and fat. Add potato and mix thoroughly; add milk and flour alternately. Add the eggs beaten lightly, chocolate, nuts mixed with spices, and lastly sift over surface baking powder, and beat thoroughly. Cook in well oiled muffin tins 20 to 30 minutes in moderate oven.

White Potato Custard (serves 4-6).—2 cups riced baked potato, 4 eggs beaten slightly, 1 cup sugar, $\frac{1}{2}$ cup fat, $\frac{1}{2}$ cup thin cream or top milk, juice and rind of 1 lemon. Mix in the order given; beat hard for 5 minutes; pour into pans lined with pastry crust. Bake in hot oven 20 to 30 minutes, or until custard is set. This makes two pies.

Variations.—Cooked in the form of patties, this will make eight.

Potato Fondant.—Using mashed potato as a base, work it into powdered sugar until it has the consistency of fondant. Flavor and form into fancy candy shapes, color or coat with melted confectioner's chocolate, and serve as Christmas candies for children.

HOT BREADS AND YEAST BREADS.

Potato Pancakes I. (serves 4-6).—12 raw potatoes grated (large), 3 teaspoons salt, 2 tablespoons milk, 2 eggs beaten, $\frac{1}{2}$ cup flour. Mix the above ingredients, beat thoroughly, and cook on hot greased griddle.

Potato Pancakes II. (serves 4).—2 cups riced potatoes, 1 teaspoon salt, 2 eggs (beaten), 2 tablespoons flour, $\frac{1}{2}$ cup milk. Mix the above ingredients in the order given; beat thoroughly, and bake on hot greased griddle.

Potato Muffins (serves 6).—4 tablespoons fat, 2 tablespoons sugar, 1 egg, 1 cup mashed potato, $\frac{1}{2}$ teaspoon salt, 1 cup milk, 2 cups flour, 3 teaspoons baking powder. Cream the fat and sugar. Add the eggs, well beaten, then the potato. Mix thoroughly. Sift flour, baking powder, and salt. Add milk and flour and beat smooth. Bake in greased muffin tins 25 to 30 minutes.

Potato Biscuit (serves 4).—1 cup mashed potato, 1 cup flour, 4 teaspoons baking powder, 1 teaspoon salt, 2 tablespoons fat, $\frac{1}{2}$ cup water or milk. Sift together flour, baking powder and salt. Work in the fat with fork or knife. Add potato, and mix thoroughly. Then add enough liquid to make a soft dough. Roll the dough lightly to about $\frac{1}{4}$ in. in thickness. Cut into biscuits, and bake 12 to 15 minutes in hot oven.

Potet Lefse (Potato Lefse).—Take left-over mashed potatoes in which cream and salt have been added while mashing. When cool add white flour enough to make a stiff dough. Taking a spoonful at a time, roll into a sheet as thin as paper, and bake on top of a moderately warm stove or pancake griddle, browning both sides well. As they are cooked, place them in a covered dish and serve hot or cold. When hot they may be spread with butter and sprinkled with sugar and rolled before serving.

Variation.—They may be spread with butter and hot lutefisk, and rolled at the table just before eating.

Potato Bread I. (two loaves).— $\frac{1}{2}$ cup hot water or milk, 2 teaspoons salt, 2 teaspoons fat, 2 teaspoons sugar, 3 cups mashed potatoes, 6 cups flour (24 ozs.), $\frac{1}{2}$ cake compressed yeast, $\frac{1}{2}$ cup lukewarm water. Put hot water, salt, fat, and sugar in bowl, add mashed potatoes, mix well. Soften the yeast in lukewarm water, and add to the potatoes when lukewarm. Add one cup of flour and knead in

thoroughly; then add the second cup, kneading thoroughly, then the remaining cups. This dough will seem very stiff and difficult to knead, but all the flour must be added, or the dough will be very soft at the second kneading. Let rise until double its bulk (about 3 hours). Knead slightly, and shape into loaves. Let rise until double its bulk, and bake in a moderate oven 60 minutes.

A larger amount of potatoes may be used in this recipe, but, as potatoes are about 75 per cent. water, if the amount of potato is increased, the hot water should be omitted. If no water is used, 4 cups of flour will make two loaves of bread. The bread will be difficult to knead, but is of very good quality.

Potato Bread II.—Recipe for 6 Loaves (by weight).—6lbs. mashed or riced potato, 4ozs. sugar, 3ozs. salt, $\frac{1}{2}$ pint fat, 5ozs. compressed yeast, 6lbs. wheat flour. Put the mashed potato into a mixing bowl, add the sugar, salt, and fat. Mix the yeast cake with the lukewarm water, add to it the other materials, and stir in the flour until the dough will not stick to the sides of the bowl. Knead until elastic, 10 to 15 minutes. Moisten the top of the dough with a little water to prevent a hard crust forming, and set to rise in a warm place. When double its bulk, cut down from the sides of the bowl, and knead again for a few minutes. Divide the dough into three portions, shape into loaves, and put into slightly oiled pans. Let rise to double their bulk, and bake in a moderate oven for about 1 hour.

Denver Biscuits.—1 quart milk (scalded and cooled), 1 cup of mashed potato, 1 cup sugar, 1 cup melted lard, 1 cake compressed yeast softened in $\frac{1}{2}$ cup water, 2 teaspoons baking powder, 1 teaspoon soda, 2 teaspoons salt, flour to make a soft sponge. Let it rise until it is full of gas bubbles. Add more flour to make a stiff dough. Cut or knead thoroughly, and put in the ice box for 24 hours. It will keep 5 or 6 days. When any of the hot breads are desired, take the amount of dough necessary, and prepare it as for any of the hot breads—buns, dinner rolls, sticks, parker house rolls, Swedish rolls, hot cross buns, or clover leaf buns.

HOME TREATMENT OF MINOR AILMENTS.

[Paper read by Miss A. Bullen at a recent meeting of the Yurgo Branch.]

Bee Sting.—Remove the sting and apply ammonia or a solution of carb. of soda, common salt, or permanganate of potash. If the sting is about the eye, mouth, or ear, do not use ammonia. If the patient is suffering from shock, keep him warm and give stimulants, i.e., hot coffee or tea or sal volatile in water.

Biliousness.—Take 2 grains of calomel at bedtime and 2 drams of Epsom salts in half a glass of water in the morning. Very little and simple food should be taken.

Sick Headache.—If this is not the result of biliousness, it may probably be due to eye trouble, and an oculist should be consulted.

Indigestion.—Ten grains bismuth carbonate, 20 grains magnesium carbonate, 20 grains carbonate of soda. Take the above mixture in milk or sodawater 3 times a day $\frac{1}{2}$ hour after meals. Do not drink with meals or within $\frac{1}{2}$ hour—longer if possible—before or after a meal. Substitute wholemeal bread for brown and take meals as dry as possible—i.e., no soups or liquid foods.

Blister.—Prick the blister with a sterilized needle and cover with boracic ointment on a rag. If caused through ill-fitting shoes, dust the socks with boracic powder.

Boils.—In adults these are usually caused through rich foods. The patient should go on a light diet for a few days. Boiled Spanish onions are beneficial. Sponge the boil several times a day with a solution of 1 part carbolic acid to 20 parts of water unless in the region of the ear or nose, when a doctor should be consulted. In children, boils are often due to malnutrition, so the diet should be looked to. An addition of chemical food is a good tonic. The skin around the affected area should be sponged with boracic acid powder 1 dram, vaseline loz. Change of air and plenty of sun out of doors will help to build up the health.

Irritated or Painful Eyes.—Bathe with 1 part of boracic acid to 40 parts of water.

Ulcerated Mouth.—Wash out the mouth with loz. borax and 1 pint water, or mix 64 grains of borax with loz. of clarified honey, and use.

Sore Throat.—Gargle with loz. borax in 1 pint of water.

Constipation.—If this is chronic, the use of an aperient over a period is necessary, the quantity being gradually diminished and then relinquished. Liquid paraffin in doses of 1 teaspoon to 1 tablespoon is a good lubricant. Cascara Sagrada tablets have a mild action and can be taken over a period of 2 months. Constipation may yield to a change of diet—fresh fruits and vegetables and wholemeal bread in place of meat and white bread. If there is straining and a wish to empty the bowels, relief can often be obtained by using a warm stool or a stool containing warm water. To train the bowels, nothing is better than regular habits. As constipation may lead to greater evils, it should never be neglected.

Slight, Clean Cuts.—Cleanse by holding under a running tap of cold water. As soon as bleeding stops, bring the cut edges together, sprinkle with boracic powder and bandage.

Grazed Dirty Cuts.—Wash the graze and cleanse with a solution of peroxide of hydrogen or ordinary turpentine. Cover with boracic dressing. If festering occurs, wash with a solution of carb. soda in water and dress with boric or cyanide gauze.

Diarrhoea.—Where the attack has come on suddenly and food is probably the cause (usually food contaminated by flies), give ½ oz. or 1 oz. castor oil, or a smaller dose in the case of children, withholding all solid food. If this does not effect speedy improvement or the pain is severe, put the patient to bed between warm blankets, with hot water or hot bran bag on the abdomen and send for the doctor. The diet should be milk and sodawater or milk and limewater. In summer, milk must be boiled and cooled in a position to which flies cannot get access. As the attack passes, arrowroot and smooth milk puddings can be given, then poached eggs or steamed fish, leading up to the ordinary diet, avoiding stringy meat, fruit skins, and similar indigestible substances. There is a heavy list of infant mortalities from summer diarrhoea in Australia, the cause being usually food contaminated by flies and unwashed fruits, though it may follow from a chill due to sudden change in the weather.

Earache.—This may be due to a boil in the ear, neuralgia, impaction of wax, or teething in children among other causes. Heat some bran in a small muslin bag in the oven and apply to the ear as hot as can be borne. If the pain is continuous, a doctor should be seen.

German Measles.—The incubation period is 14 days. Symptoms: cold, running nose, sore throat, pains in back and legs, glands swell in neck. A rash quickly appears on face and neck, spreading down over the body. It lasts from three to five days. Put patient in bed and keep there until rash fades. Give light, digestible food, such as milk, junket, milk puddings, custard, &c., until appetite returns. Keep patient away from other children until all catarrhal symptoms in throat and nose have disappeared. Children exposed to infection should remain apart for 20 days.

Growing Pains.—These pains felt by children in the bones and around the joints are not due to growth, but are in most cases symptoms of rheumatism, and should have attention by a doctor.

Influenza.—Do not wait until it is impossible to perform ordinary duties, but as soon as the cold symptoms appear take a hot bath and get into a warm bed at once. Keep to a diet of slops until the temperature drops, and keep the bowels working freely with cascara. When the acute stage is passed, a light varied diet can be substituted, aided by tonics. If the attack has been severe, the patient should remain in bed four days after the temperature returns to normal. After influenza the patient is apt to suffer from marked depression, and a holiday by the sea is advised.

Cold.—It is as well to follow the directions for influenza by going to bed and confining one's diet to liquids for a day at least, until sure that it is no more than a cold. Do not go to public meetings until the risk of infection is over. Colds and influenza are highly contagious.

Tetanus or Lockjaw.—The cause is a microbe introduced through some wound or cut in the skin. For prevention, all wounds should be thoroughly cleansed at once. Where there is stiffness in the muscles in the region of the wound or in the jaw or neck, the patient should be given a warm bath and put to bed and the doctor sent for.

Measles.—Incubation period seven to 14 days. Resembles a severe cold in the initial stages, with temperature running up to 100deg. to 103deg. Three or four days later red spots appear on the neck, face, and body, and small pink spots inside the mouth. The rash begins to fade in three to four days and scale—convalescence is rapid. The chief danger is to the lungs and respiratory passages—a doctor should be informed if the child becomes croupy. As measles is highly contagious before the rash appears, the patient should be isolated in a large airy room at a temperature of about 65deg.

Slops should be given until the temperature drops, after that light foods. The patient should not leave bed until the temperature has been normal for seven days. Any complications need careful attention—the most serious being broncho-pneumonia, and requires constant medical attention. The safeguarding of young and delicate children from infection is of great importance.

Mumps.—Incubation period two to three weeks, quarantine 25 days. Symptoms are pain in the glands and feverishness, swelling of the parotid gland near the ear. The fever passes away in four to five days, and the swelling begins to subside in 10 to 12 days. The patient should be kept in bed for a week or 10 days, and in his room for another week. The diet should be fluid. A warm poultice or cotton wool should be applied to the swollen face; the mouth frequently rinsed with warm water containing a little permanganate of potash. Everything should be disinfected when the patient leaves the room—this applies to all contagious diseases.

Hives or Nettlerash.—In older children or adults they may be due to eating shellfish, mushrooms, cheese, eggs, pork, pickles, pastry, or strawberries; wearing rough flannel next the skin, violent emotion, worms, goutiness, bites of insects, use of cosmetics and hair dyes, and the taking of certain drugs. In treatment, the cause must be ascertained. If acid indigestion, take 10 to 15 grains of bicarbonate of soda in a wine-glass of water. If the disorder is severe in children with accompanying digestive disorder, give an emetic, $\frac{1}{2}$ teaspoon mustard in tumbler of warm water, and when this has acted 3 teaspoons of castor oil. Regulate the diet, restricting to milk at first, experimenting to find out which food seems to disagree. To relieve the itching, dissolve 1 teaspoon of carbonate of soda in a tumbler of warm water and bathe the affected parts. A simple dusting powder consists of 1 dram of zinc oxide and 1oz. starch. Sometimes a week in bed on a milk diet will cure the eruption.

Prickly Heat.—Bathe in a solution of 1oz. of bicarbonate of soda to each gallon of water, rubbing the skin afterwards with lemon juice or carbolic lotion (1 part carbolic to 60 parts water), or dust with equal parts of oxide of zinc, boric acid, and starch.

Scarlet Fever.—Symptoms: The onset is usually sudden. The temperature rises rapidly to 103deg. and more. The tongue is furred, the throat sore and vividly red, and the pulse rapid. The patient looks dull and stupid. Usually there is vomiting, and in younger children convulsions are frequent. The face is flushed. From 24 to 36 hours after the first symptoms the rash breaks out, generally on neck and chest. It consists of very fine red spots, each surrounded by red shading, so that the whole skin of the body becomes bright red. The chin and lips remain pale. Sometimes the rash occurs in patches and is mistaken for measles. The tongue in the beginning is covered with thick white fur, except the tips and edges, which are bright red. In a few days the coating falls off, leaving the tongue red, dry, and covered with redder spots. After three or four days the body rash begins to fade and the skin commences to peel, the process lasting three weeks or longer. Severe complications are possible, but in the lighter cases much the same treatment is used as in measles. Exceptional symptoms call for special medical treatment.

Convulsions.—In severe cases the face and limbs are contorted, the face is either dark or pale, there may be frothing at the mouth, and the tongue is often caught between the teeth and bleeds. They may occur at the beginning of many diseases, such as fevers, pneumonia, and influenza, but are often due to overloaded stomachs and some irritant in the bowels. They are frequently seen during teething, but apart from some digestive trouble, teething alone does not bring on convulsions. Place the child in a warm (not hot) bath, the temperature such as can be borne by the bare elbow. Apply cold water to the head. After the bath, place the child in a warmed bed and give a dose of castor oil. The food should be of a very light nature until all symptoms of convulsions have gone.

Whooping Cough.—The first symptoms are those of an ordinary cold with spasmodic coughing. This may last for a few days, or even a fortnight before the characteristic "whoop" develops. As the child cannot take air into its lungs at the proper rate, its face grows blue, there is a long, deep inspiration which causes the "whoop." The child should be isolated and either clothed in flannel or kept in bed, though in really warm weather they are better out in the sun. By attacking the early "cold" the disease may be shortened. The diet should be plain and nutritious, all rich food, such as meats, eggs, and foods fried in fat should be avoided. Fruit is beneficial. If the child is in bed chest fomentations three times a day should be given, cover warmly or add a warm bran bag after. The vapour from 1 teaspoon of compound tincture

of benzoin added to 1 pint of boiling water and inhaled brings relief. A hot bath and chest fomentations at bed time are beneficial. The child should drink water freely. If the child is running about, try some shredded garlic in the shoes, taking care there is something, such as muslin, between the bare feet and the garlic, or the feet will blister. It will cause the child's breath to smell, but should cure the cough very rapidly.

In all cases of contagious diseases everything used by the patient and everything in the room should be disinfected. It is a good plan to hang a sheet which has been dipped in some disinfectant in the doorway.

CHART FOR THE NURSERY.

Illness.	Time after Infection after which Illness Begins. Days.	Infection Ceases.	Isolation
			Period after Exposed to Infection. Days.
German measles	7-21	10 days after rash appears	21
Measles	10-14	2 weeks after rash appears	16
Mumps	10-14	3 weeks, and only then is swelling has subsided a week	24
Whooping cough	1-14	In 6 weeks from first "whoop" if cough has ceased 2 weeks	21
Chickenpox ..	11-24	After every scab is off	29

1 dram equals 1 teaspoon.

AUBURN (Average annual rainfall, 24 00in.).

April 6th.—Attendance, 19.

HOME NURSING.—Paper read by Mrs. Burfield—"For a fraternity of women who live in the country, sometimes many miles from a doctor, one feels that perhaps the advice about choosing a well ventilated room, free from draughts, and containing as little furniture as possible, &c., while being very good advice, might well be left to the good sense of the housewife, and a few suggestions as to prevention of illness and treatment of minor accidents be more useful. Burns and scalds are wounds needing very early treatment, for the exclusion of air to the part is very important. For this reason the white of egg is very useful, and is generally on hand, in which case break the egg, remove the yolk, and pour the white over the affected part, covering it with clean linen and bandaging it. This will relieve the pain and heat, and the burn can later be dressed with sterilized vaseline. The most effective treatment for burns, however, is the application of picric acid. A bottle of this can be kept on the kitchen mantelpiece with a jar containing clean linen and bandages, and is ready for any emergency. Soak the linen in the picric acid and apply very wet to the burn, cover with cotton wool, and bandage. It will give immediate relief. If the burn is extensive, there is always a certain amount of shock to be treated, which should be done by putting patient to bed, applying hot bottles to feet (being very sure to cover them well to prevent another burn), and giving the patient a hot drink. Burns to the eye by splashing fat or lime, &c., are best treated by dropping a few drops of castor oil into the eye. Sties in eyes can be most painful, and if, when they first appear, the eyelash in the centre of the swelling can be removed, and the lid frequently rubbed with castor oil, it will often relieve the trouble before it develops. When the swelling and redness persists, fomentations of Epsom salts will be found most beneficial. For children who have long distances to go to school in hot weather, and are prone to have trouble with their eyes, dark glasses are advised. Colds, if taken in the very early stages, can often be warded off by taking ammoniated quinine and cinnamon—2 tablets of quinine with 10 drops of cinnamon for adults, and half doses for children. Cuts and abrasions after being cleansed (with boracic lotion 1 teaspoon to 1 pint, or 1 teaspoon of salt to pint of boiling water) should be painted with iodine. Clean linen kept for treating wounds can be aseptic by ironing with a very hot iron. Any wounds caused by rusty nails or farm or garden implements should be taken to the nearest doctor for injection against tetanus, which is very prevalent. Croup in children can be relieved by giving the child a spoonful of olive oil with sugar sprinkled on it. If the first dose is ejected, follow it immediately by another and the croup will be relieved. This is a more simple remedy than the 1, 2, 3 compress, which is often used effectively, consisting of 1 tablespoon of methylated spirit, 2 of vinegar, and 3 of water. If a cloth is wrung out in this solution and wrapped around the throat it should be covered with a dry cloth to prevent the bed clothes being wet. In nursing case of sickness at home it is often a great anxiety to the mother when the patient refuses to eat, but it must be remembered that this

is often Nature's way of saying that food would be harmful to the complaint. Milk and eggs contain all the elements of food that the body requires. For those who object to drinking milk, a spoonful of Bovril can be added to a cup of milk and taken as soup, or if given as a drink, should be taken to the patient in a cup instead of a glass, to disguise the milky appearance. Milk jellies can be made very tempting, and tea, coffee, or cocoa may be made with boiling milk instead of water. Drinks of water in between these milk meals will relieve and cleanse the dry mouth, and will also tend to increase the flow of urine and thus dispose of much of the waste products of the body. Keeping the bowels open, either by a mild aperient or enemas of soap and water, will often remove the cause of all the trouble, except in cases of severe abdominal pain, which, if it does not clear up after the application of hot fomentations and cannot be traced to eating green fruit or indigestible food, should at once be reported to a doctor." (Secretary, Miss L. Dennison.)

BALUMBAH.

April 4th.—Attendance, 14.

Mrs. H. Van Heythuysen gave an address, "Scalds and Their Treatment." Immediately on scalding wrap the affected parts in soft cloth dipped in olive oil, which must be used plentifully to prevent sticking. It is very necessary to keep the air off the scald, as this causes it to burn and sting. Wherever it is even slightly red or inflamed, be sure to put on plenty of oil. Keep up this treatment for two or three days, then gently smear on zinc ointment or vaseline and keep well wrapped in lint. If, by any chance, the scald is blistered, do not break the blisters, but keep on with the oil treatment. Breaking the blisters causes them to sting much more than if left to break themselves. (Secretary, Miss V. Wohling.)

THE USE OF DRIED FRUIT IN THE HOME.

[Paper by Mesdames D. McFEAT and E. STACY.]

There is a wide variety of fruit grown in this district, and drying enables us to have fruit all the year round, which is a great help to the housewife with the problem of variety for the daily menu. Many kinds of fruit can be dried—nearly all vine fruits, several varieties of stone fruits, also apples, pears, &c. The vine produces one of the most nutritious of all fruits, and grows very luxuriantly in Clare. The vine embraces sultanas, currants, and lexias. The large, thin skinned grapes are used for puddings, and dried on the stems in clusters make an ideal dessert. Raisins are a life-giving food; 1lb. of raisins has been proved to represent an energising food value equal to 1½lbs. of beef, 6lbs. of apples, 5lbs. of bananas, 4½lbs. of potatoes, 20 eggs, or 4lbs. milk. The remarkable food value of raisins makes their daily use a blessing of health.

To prepare the fruit for cooking, a good plan is to wash and pick it as soon as the grocer has fulfilled the order. When quite dry store in tins or jars, and it is ready for use when required. Breakfast dishes can be made more nutritious by the addition of raisins. For oatmeal porridge, add raisins 10 minutes before the porridge is done. Weeties, grape nuts, crispies, &c., are improved by adding plump seeded raisins or sultanas. To plump raisins, put required quantity in small basin, and cover with boiling water; place plate on top, and stand until cool. Raisin bread toasted is delicious for breakfast. Put raisins in bread puddings—it will make a plain dish into a more healthful one. Add a few raisins to the seasoning for poultry, and you will never again omit them. For those who have vines growing a good plan is to dry the fruit. Raisins and sultanas are dried in small bunches, dipped in a solution of caustic soda, and put on trays to dry in the sun. Currants are dried in the sun without any preparation, but are more trouble to clean. They are best left to the factory process of stemming and brushing, and are then ready for use. All dried vine fruit contains vitamins—fruit sugar (75 per cent. in raisins), iron (a splendid tonic), and laxative juices. Dried vine fruit minced with lemon peel and juice of lemon makes an excellent sweet, minced with the

addition of lemon juice, can be used for sandwiches. Savories can also be made with these fruits and other ingredients. A few recipes are added that may be of use to the housewife looking for a change.

Drying Fruit.—Dehydration means artificial heat. Taking the apricot, as an example:—First, it must be just at the right stage for picking—not too ripe nor too green on account of the sugar substances. They have to be cut in halves and put on trays. These trays are packed and put into airtight places, and go through a process of sulphuring, which gives them a bright color. From there they are then put into large boxes for a couple of days; then the packers pack them between grease-proof paper into boxes for sale. Most fruits go through a similar process; where the apricot is sulphured the prune is dipped. When fresh fruit cannot be obtained dried fruits are very much appreciated.

Apricots are a beautiful fruit, and very nice when dried. When dried by modern methods they are almost like fresh fruit when soaked in water until soft, and can be used for pies and tarts, and also made into jam. Dried plums or prunes have a very high food value. They can be used for pies and tarts, and make a very nourishing breakfast dish. Soak overnight in cold water, boil until soft, serve with sugar and cream; rice may be added. Prunes minced and mixed with senna powder and glycerine makes an excellent laxative. To cook dried prunes: Wash thoroughly, soak in water to cover from 10 to 24 hours, adding more water if necessary. Simmer gently in the water they are soaked in until tender (about 20 minutes); add sugar, and cook 5 minutes longer. To 1lb. prunes use 1 pint of water and 4ozs. sugar. Apples and pears are also dried, and are a great help in the winter. Dried apples are very good for pies and puddings. An improvement is to mix dried apples with melon for pies. All dried fruit should be well washed and soaked in cold water for at least 12 hours. Dried pears are best steamed until soft. If very sweet, the addition of lemon juice is an improvement. Dried pears can be eaten without any preparation as a dessert. Quinces can also be dried, and a few added to dried apple pies give them a lovely flavor. Dried figs are a very useful fruit. For home drying, make a fairly strong syrup; put in the figs, and boil 2 hours; drain, and place on trays to dry them in the sun. When dry, make a very strong syrup, and dip the figs again while boiling, and dry quickly. These will keep a long time, and are useful for cakes and puddings.

CLARE (Average annual rainfall, 24.56in.).

February 3rd.—Attendance, 25.

DRIED FRUIT RECIPES.—Supplied by Mrs. D. McFeat:—**Apricot Cakes.**—Weight of 6 eggs in butter, 2 in sugar, 2 in cornflour. Method: Beat butter and sugar to a cream, add 4 eggs well beaten, enough S.R. flour to roll out to a smooth paste. Stew dried apricots, sweetened with sugar. Place apricot between rounds of paste and bake in a moderate oven. When cold, sprinkle with cocoanut. **Dried Apricot Cake.**—2 eggs, their weight in butter, 1 sugar, 6ozs. flour, 2ozs. dried apricots, $\frac{1}{2}$ teaspoon baking powder. Method: Beat butter and sugar to a cream. Sift the flour and divide it into two portions. Break 1 egg into cake, add 1 tablespoon flour. Beat well. Stir in half flour. Repeat with other egg. Add fruit to mixture. Leave a little flour to mix with baking powder and add this last. Bake from 1½-2 hours. Prunes, pears, preserved ginger, and cherries may be substituted. **Dried Apricot Jam.**—2lbs. apricots, wash well and leave to soak in 13 cups cold water overnight. Then put on to boil and boil for about $\frac{1}{2}$ hour; add 7½lbs. sugar and boil until clear—about $\frac{1}{2}$ hour. **Dried Fruit Dessert** (Mrs. E. Stacey).—Soak overnight 2 cups dried apricots, 1 cup each peaches and nectarines; have some cooked apples; next day just boil, with sugar to taste, the dried fruit and take skin off peaches. Make a champagne pastry (no cinnamon); line a flat dish and put all fruit in and spread it on; put another pastry on top. Mix icing sugar with water and brush on top, sprinkle with mixed nuts or cocoanut and bake. This will burn quickly; use a moderate oven. Cut in squares and serve hot with custard. Makes a good dessert or is very nice eaten cold. **Aunt Betsy Pudding.**—2 cups plain flour, 1 cup bread crumbs, 1 teaspoon each salt and soda, $\frac{1}{2}$ cup sugar, $\frac{1}{2}$ packet spice, 1 teaspoon ginger, 1 cup each currants and raisins, lemon or orange peel, 1 cup hot water, 2 tablespoons dripping. Method: Mix flour, salt, and

soda sifted, add bread crumbs. Mix spices with sugar, add to flour, then fruit. Melt dripping in hot water and mix pudding. Boil 3 hours. *Sago Plum Pudding*.—1 cup breadcrumbs, $\frac{1}{2}$ cup sugar, 2 tablespoons sago (soaked over night in enough water to cover), 2 tablespoons butter, 1 cup seeded raisins or mixture currants and sultanas, 1 level teaspoon soda dissolved in boiling water. Method: Mix dry ingredients together, stir in 1 cup milk or enough to mix well and allow for swelling while cooking. Pour in greased moulds and boil 3 hours. *A Savory*.—To 1 cup of seeded lemons or sultanas add 4ozs. to 6ozs. cold ham (minced), 2 or 3 tablespoons cucumber pickles, salt and pepper to taste. Stir in sufficient cream or mayonnaise to bind, spread easily. Serve on triangles of toast as a savory, or on lettuce leaf for luncheon, or serve between thin slices of brown bread as a sandwich. *Vine Fruit Pie*.—1 cup each sultanas, currants, and seeded raisins, 2 pieces shredded lemon peel, 2 diced apples, $\frac{1}{2}$ cup sugar, $\frac{1}{2}$ cup water, nutmeg. Method: Put in saucepan and simmer $\frac{1}{2}$ hour. Line tart plate with paste, spread with filling, cover with paste, and bake 30-40 minutes. *Dried Prune Chutney*.—2lbs. prunes, 1lb. green apples, $\frac{1}{2}$ lb. green tomatoes, 2 or 3 large onions, $\frac{1}{2}$ lb. raisins, $\frac{1}{2}$ oz. ginger, $\frac{1}{2}$ lb. brown sugar, $\frac{1}{2}$ lb. salt, 1 teaspoon mustard seed, $\frac{1}{2}$ teaspoon cayenne, 3 pints vinegar, 1 teaspoon powdered cloves. Method: Soak prunes overnight, wash and drain, cut open and remove stones. Cut onion and apples small, slice tomato; place all ingredients in preserving pan and cook 3 or 4 hours. Stir occasionally. Try a little on a saucer and if there are no watery particles, it is ready to bottle while hot. Keep for a few weeks before using. *Dried Prune Jam*.—3lbs. prunes, 3 quarts water, 8lbs. sugar, juice of 4 lemons. Method: Wash prunes and soak overnight in water. Next day boil until soft, add sugar and juice of 4 lemons. Bring to boil again. Boil 1 hour or until a little placed on a cold saucer will set in a few minutes. Remove from fire, bottle while hot, cover when cold. *Prune Brown Betty*.—2 cups soft breadcrumbs, 2ozs. butter, $\frac{1}{2}$ cup brown sugar, $\frac{1}{2}$ teaspoon each cinnamon and nutmeg, juice and grated rind of $\frac{1}{2}$ lemon, 2 cups prunes stoned and cut up; $\frac{1}{2}$ cup of prune juice according to dryness of crumbs. Method: Melt butter and stir into crumbs, put layer of crumbs in buttered piedish, then layer of prunes; sprinkle with some sugar and spices. Repeat layers until dish is full, making the top layer of crumbs. Pour prune juice over the mixture and bake in a moderate oven 30 minutes. Cover during the first 15 minutes, then allow to brown. Serve with sauce or cream.

The meeting of March 3rd took the form of a Question Box. (1) The member who asked the best way to prevent sauce from burning was advised—(a) to grease the bottom and sides of pan well; (b) to put several glass marbles into pan, which, when contents of pan begin to boil, keep up a constant movement; (c) or to put two florins into pan, these having previously been scalded. (2) Which is the best way to take tar out of wool carpet? Advised to treat with eucalyptus. (3) How to put dressing back into material after washing, which goes limp and creases? A little liquid glue in the rinsing stiffens things. (4) How to keep brown sugar from going hard? Must be kept perfectly airtight after being rolled in a damp cloth. (5) Which is the best way to wash new blankets? (a) Lux; (b) borax and cloudy ammonia; (c) 2 tablespoons soft soap, 1 tablespoon each borax and ammonia dissolved, add to water, stir well, and allow articles to soak. (6) How to keep an airtight cushion when not in use? Rub on French chalk, free cushion from air, hang in a dry place. (7) How to store dried fruits to keep them free from the moth as long as possible? Scald with boiling water and put into new calico bags. Hang to dry. (8) How to stop the grub from getting into tomatoes? Spray before coming into flower with arsenate of lead. (9) How to pot butter? When butter is thoroughly clean, work several times a small piece of saltpetre with a teaspoon of sugar into the butter. Press each layer of butter down well, put thick layer of salt on top. (10) How to remove an inkstain from an Arras tablecloth, also from carpet? Sour milk and citric acid have been tried; took some colour out, but stain is still there. Advised to allow the article to remain in cold water for a length of time, repeat when water is coloured. (11) How to make a non-slippery floor polish. Members used a good mop-oil. (Secretary, Mrs. W. McKendrick.)

COONAWARRA.

Attendance, 50.

The younger members of the Branch took charge of the meeting, and the following papers were read, visitors being present from Penola and Kalangadoo:—

SAVORIES (Miss O. Lear).—"So important a place do savories now occupy in meal planning that all housewives who are most desirous of pleasing are now making a serious study of them. Even the lightest and creamiest of cakes cannot shake the popularity of savories for afternoon or evening parties. Tempting savories are greatly appreciated by the majority of people, and may be served either hot or cold. Introduced as a dinner dish, a savory is very much relished. Stew is rendered more palatable if savory balls are dropped in and boiled for half an hour before serving. Small

individual pyrex ware dishes are used by many hostesses for serving savories at dinner or supper. Savories served in such dishes, or small scallops can be prepared some time previous, placed ready on an oven slide, and put in a moderately hot oven about 15 minutes before required. Then each small dish is placed on a plate, covered with a dainty d'oyley for convenience in handling. These scallop dishes are, of course, best served at a small gathering—unless the hostess possesses a very large number of small fire-proof dishes. The dishes must not be too full—all savory containers should be small and dainty. Savory dishes must be attractively garnished with decorations that blend well with the flavour of the dish, and a contrast in colour should be made between the dish itself and the garnish. Capers, olives, gherkins, small strips of beetroot, tomato, celery shoots, lettuce (small leaves or shredded), stuffed olives, and shrimps are some suggestions for garnishing. Small savory cases can be made from numerous mixtures, such as cheese straw, choux pastry, rough puff pastry, short crust, and cheese pastry. Cold savories are particularly appetising during summer, and in very hot weather are generally preferred to sweet cakes. Savory salads at this time of the year greatly assist in overtaking the fugitive appetite of the peckish quicker than anything. In hot weather they are piquant, fresh, and wholesome, and easy to make. Not the least important item at a party is the supper, and many a hostess finds the selection of suitable dainties rather a task. One cannot go wrong with savories, for careful cooks and popular hostesses know that delicious flavours which tempt the appetite and delight the taste have a satisfying distinctiveness and richness of flavour with which they may win admiration of guests. Delicious and quickly prepared savories can be made with meat pastes, cream cheese, and home-made fish pastes made up and kept for emergency purposes. Men, especially, are fond of savories, and some consider a dinner quite incomplete without this agreeable relish, which offers such a pleasing variation. They are always served in very small proportions, therefore daintiness is essential. It is essential for a savory to be piquant, as flavour is the main thing. The preparation of savories is simple, and only care is required to present a dish which is tempting and appetising. The following recipes are useful and do not require a great deal of time in preparation:—

A Savory Dish.—2lbs. mutton chops, pare off all fat, roll in flour, place in casserole or in a saucepan with a good lid. Mix 1 tablespoon flour, 1 small teaspoon mustard, 1 tablespoon each of tomato sauce and Worcestershire sauce, and a little water, making sufficient liquid to cook meat. Add meat and simmer gently for about 2½ hours.

Savory Balls.—6ozs. flour, 1 teaspoon baking powder, 2ozs. suet, pinch salt, 1 teaspoon chopped parsley, pinch of dried herbs. Chop suet finely, add the ingredients, and mix to soft dough with water. Form into balls and cook in stew for 20 to 30 minutes.

Macaroni and Tomatoes.—4ozs. macaroni, 3 tomatoes, 3ozs. butter, 1 onion, 2ozs. grated cheese, bread crumbs, cayenne, and salt. Wash macaroni and put in salted boiling water. Boil 20 minutes, then drain. Cut onion in thin rings and put in pie dish in oven with half the butter. Pour boiling water over tomatoes and take off skin. Cut in thin slices and add to onion; then add macaroni, season with salt and cayenne. Sprinkle cheese over top, then few crumbs, and lastly remainder of butter in small pieces. Cook in quick oven 20 minutes.

Tomato Savory.—Cut tomatoes into rounds and fry in a little butter. Have ready some small rounds of hot buttered toast or fried bread, put a slice of tomato on each round (they should be about the same size) and cover thickly with grated cheese. Decorate the top with a few capers. Put in oven a few minutes and serve very hot.

Savory Eggs.—2ozs. fresh bread crumbs, 2ozs. grated cheese, 1 teacup milk, 3 or 4 eggs, pepper, and salt. Boil milk and crumbs 2 or 3 minutes, then pour into sandwich tin which is well buttered. Drop in eggs, sprinkle with pepper and salt, then sprinkle the cheese all over, add small pieces of butter and bake until eggs are cooked and top is browned.

Welsh Rarebit.—3ozs. grated cheese, 1oz. butter, 2 tablespoons cream, 1 egg, ½ teaspoon made mustard and salt. Put cheese in saucepan with butter, cream, and seasoning. Stir over fire until smooth, beat in a well whisked egg, and pour over neat pieces hot buttered toast. Serve at once on a hot dish.

Savory Tarts.—½lb. cheese, 1 egg, pastry, ½lb. bacon, 1 onion, pepper and salt to taste. Make a good short crust and roll out about ¼in. thick. Line small patty tins with pastry and prepare the following mixture:—Chop the onion finely and put on to boil. Cook until tender. Drain well and mix with the diced bacon, grated cheese, and egg. Fill the patty cases with mixture and bake in moderate hot oven until golden brown and pastry cooked through. Serve hot for afternoon teas, supper, or Sunday night tea.

Salmon Patties.— $\frac{1}{2}$ cup chopped salmon, pepper and salt, $\frac{1}{2}$ cup thick white sauce, 1 dessertspoon cream. Mix salmon with white sauce, pepper, salt, and cream. Fill pastry patty cases with this mixture. Garnish each patty with a sprig of parsley and 2 capers. Serve hot or cold.

Cold Savories.—Mix Marmite and butter together and spread on plain biscuit, then sprinkle with chopped nuts. Butter plain biscuits and sprinkle with chopped hard-boiled eggs and parsley, or chopped capers on egg. Decorate with half an olive each end of biscuit. A small patty case filled with celery and mashed cheese, or mushroom and cheese.

Butter plain biscuits and sprinkle with chopped pickled walnuts. Fry fingers of bread in butter and serve cold with a slice of tomato and a sardine on each.

Spread a mixture of fish or other paste and butter on brown or malt bread, and sprinkle with chopped nuts. Roll each slice and fasten with a wooden toothpick until required.

Bubble Bread.—1 tablespoon butter, 1 cup flour, small teaspoon salt, 1 tablespoon grated cheese, $\frac{1}{2}$ teaspoon cayenne pepper. Rub butter into flour, &c., and mix to a stiff paste with milk. Roll out like paper.

Cheese Filling for Choux Pastry, Etc.— $\frac{1}{2}$ cup grated cheese, $\frac{1}{2}$ cup milk, cayenne pepper and salt to taste. Put the grated cheese, cayenne, and salt into a basin, and pour over the milk. Leave standing about $\frac{1}{2}$ hours and the milk will combine to make a smooth cream cheese. Mix lightly and use the filling for cheese eclairs, &c. If too rich with cheese, a little whipped and seasoned cream can be added. This will make the cream cheese go much further. This cream cheese can be used for either hot or cold savories.

SALADS (Miss R. Winton).—Salads are a valuable part of the daily food, especially in summer. They are frequently eaten with cold meat or fish, and act as an appetiser when attractively arranged. The mineral salts and acids contained in young, crisp leaves of vegetables prevent acidity of the blood, and help to regulate bodily functions. Salads are of three varieties:—1. (Uncooked) Chiefly lettuce, cucumber, tomato, cress, celery, and radish. 2. (Cooked vegetables) Potato, beetroot, asparagus, peas, beans, and cauliflower. 3. (Fruit) A mixture of fruit in season.

General Rules.—All plants must be young, sound, and crisp. All uncooked vegetables must be well washed to rid them of insects and dirt, and dried by shaking in a clean cloth without bruising the leaves. Salads should be made just before serving, that they may be fresh and crisp. Flavours should be blended carefully, no one predominating. Tear lettuce with the fingers or cut with silver knife, never use steel. Cold cooked vegetables left over from a meal may be cut into small pieces, or fancy shapes, and made the basis of a salad with garnishes and dressing. Colours should be chosen with care to make the salads attractive. Serve in a glass or china bowl. The dressing is put separately in a glass jug.

Garnishing.—A plain salad may be made more appetising by the addition of a garnish. This may consist of vegetables of contrasting colour cut into dice. Slices of cucumber, tomato, or beetroot, hard boiled eggs, parsley, young lettuce leaves, capers, gherkins, &c. Salad dressing is a sauce added to increase the food value of the salad. It should contain vinegar to soften the cellulose, oil or cream to add fuel value.

Beetroot Mould.—Ingredients: 2 bunches of beetroot, 1 small lettuce, 2 dessertspoons gelatine, 2 cups hot water, pepper, salt, and vinegar. Directions: Cook beetroot until tender, peel and cut into slices, line a fluted mould with the slices, then fill centre with small dice-shaped pieces of beetroot. Dissolve gelatine in hot water, pour over beetroot and allow to set. Garnish with shredded lettuce and sliced tomato. Serve with mayonnaise dressing or vinegar.

SANDWICHES (Miss D. Modistach).—*Sandwich Butter.*— $\frac{1}{2}$ lb. butter, $\frac{1}{2}$ teaspoon white pepper, juice of 1 lemon, nutmeg, cayenne and salt to taste, 2 small sprigs parsley. Wash and mince parsley, add to above ingredients, except lemon juice. Work together with wooden spoon until mixture is green, gradually add lemon juice and work well together. It takes 10 to 15 minutes to blend ingredients. If a deeper green is required, add more parsley. Drain off any liquid before using.

Cheese and Raisin.—Mince cheese and raisins together and spread between buttered slices. *Mock Chicken.*—Take 1 egg (hard boiled), small piece onion, $\frac{1}{2}$ teaspoon mixed herbs, 1 teaspoon butter, salt and pepper to taste. Chop all together finely and spread between thin slices bread and butter. *Cheese and Tomato.*—Grate cheese and slice tomato thinly, arrange between buttered slices, flavour with salt and pepper. *Gherkin Sandwiches.*—Cut gherkins finely and place between buttered slices. *Raisin and Ginger.*—Equal quantities of raisins and ginger minced together with a squeeze of lemon juice. *Banana Sandwich.*—Cut banana finely and spread between buttered

slices. *Cheese and Almond*.—Grate cheese and mince almonds. Spread between buttered slices. *Ginger, Date, and Nut*.—Mince preserved ginger, nuts, and dates together, add a little water, and mix well. Spread between buttered slices. *Apple Sandwich*.—Grate a ripe apple finely. Blanche and halve some almonds. Mix with apple and arrange between slices of buttered bread; add a little whipped cream if desired.

QUESTION BOX.—The meeting held on March 21st took the form of a Question Box. *Attendance, 35. Before varnishing new woodwork apply a coat of glue, then one coat of varnish will be sufficient.

Melon and Fig Jam (Mrs. Modistach).—7lbs. figs, 5lbs. melon, 9lbs. sugar, juice of two lemons; preserved ginger may also be used.

Cocoanut Cakes (Mrs. R. Redman).—3 tablespoons butter, 1 small cup sugar, $1\frac{1}{2}$ cups self raising flour, $\frac{1}{2}$ cup cocoanut soaked in $\frac{1}{2}$ cup milk for $\frac{1}{2}$ hour, 2 eggs. Cream butter and sugar, add eggs separately, then other ingredients. (Secretary, Mrs. F. Skinner.)

MANGALO (Average annual rainfall, 14in. to 15in.).

March 14th.—Attendance, 16.

COWS ON THE FARM.—Paper read by Mrs. A. Turner:—"Cows on the farm are a necessity to a household, particularly when there are children in the home. It is always best to select a good type of cow. In many instances a farmer has to begin with the best animals that are procurable in the district, but from then on it is his work to select the best heifers—those that are of a quiet and contented disposition. The cows should be fed twice a day and have a shed in which to be milked and fed. They will then give much less trouble in milking and feeding. The shed and all utensils used with milk must be kept clean. The main points in keeping cows are—select good types of heifers, feed twice a day, keep shed and yard clean, and particularly buckets, pans, separator, and any utensils used in the process."

April 11th.—Attendance, 17.

FIRST AID HINTS.—Mrs. H. Klingberg contributed the following paper:—"No one has any wish to have the opportunity of assisting at accidents, nevertheless it is an advantage to know what to do in case one is called upon to act whilst waiting for the doctor. Some of the first things to do are—remove the cause of injury or damage whenever possible. Severe haemorrhage must receive the first attention, no matter what the other injuries may be. The patient must be in a position in which breathing is possible; the air passages must be free from obstruction. A restful position of the body will assist the vital functions; support of the injured part will help to prevent further damage, and is essential in the case of fractured limbs. After an accident keep the patient warm to prevent the fall of temperature below normal. When the skin is broken the wound should be promptly covered with a clean absorbent dressing. Poisons swallowed should be got rid of, or when that is inexpedient neutralised. Strong tea acts as a neutraliser of many poisons, and is always safe. A handful of tea should be thrown into a kettle and boiled. Clothes should not be taken off unnecessarily, but when it is needful to remove them, the following rules will be found of service in serious cases:—Remove the coat from the sound side first, and, if necessary, slit the seam of sleeve on the injured side. The shirt and vest should be slit down the front and removed. Trousers should be slit up outer seams, and boot slit down back seam and unlaced. The sock should be cut off. It is incorrect to suppose that alcohol is the only form of stimulant, and far too frequent use of spirits is made to restore a patient after an accident, often with serious results. The safest rule is to wait the arrival of the doctor, and when the patient is able to swallow, strong tea or coffee or milk as hot as can be drunk may be given. Smelling salts may be held to the nose." (Secretary, Mrs. B. Coles.)

MORCHARD (Average annual rainfall, 13.59in.).

April 6th.—Attendance, 14.

THE FARM DAIRY.—Paper read by Mrs. B. McCallum:—"A dairy is necessary for the preservation of food during summer. The following are the details of a dairy under construction on our homestead:—The dairy is situated about 4ft. from the verandah, almost opposite the kitchen door, the porch for the steps of the dairy connecting it to the verandah, thus enabling one to step from the verandah on to the steps of the porch, which are of cement half way down, and where they enter the dairy the steps will be constructed of wood with a hand rail. The length of the

dairy is 12ft., width 7ft. 6in., and depth below surface level 6ft. The reinforced cement concrete wall below surface level is 4in. in width, and a 14in. stone wall is built above surface level to the height of 3ft. with gable ends. The roof will be of galvanized iron steep gable design, ceiled with matchboard. For ventilation there is a window 2 x 2 x 3 inches in the end wall of the dairy, two fairly large air bricks each side covered with wire gauze on the inside, and a panel of gauze in the door, which is opposite the window. Under the window across the end of the dairy there is a cement shelf 18in. wide and about 2ft. 6in. high, with the outer edge raised a few inches to allow it to hold water for the purpose of placing in it cream, butter, jellies, &c., during hot weather. This ledge, or shelf, should prove a boon during a heat wave. The dairy is plastered with lime and cement mixture, and has a cement concrete floor.'

LEMON YEAST (by Mrs. F. S. Twigden).—"Boil a medium size potato, when cooked strain off water and mash potato well. Gradually mix water back on the mashed potato, mix in $\frac{1}{2}$ cup sugar, let cool, then mix $\frac{1}{2}$ cup flour, or more, according to the quantity of water. Strain in the juice of 3 lemons and mix to the thickness of batter. It should be put into a wide mouthed jar and covered to keep it free from flies and dust. This yeast will take 3 to 4 days before ready for use the first time, then after it has started, make it at dinner time and it will be ready to mix bread at night, after the evening meal. *To Mix Bread.*—To 6lbs. of flour add 1 handful of salt. Mix thoroughly into the flour 1 large breakfast cup of yeast, sufficient warm water to knead the bread into a nice dough, and knead well. Bread should be set over night and covered well to rise. When well risen, make into 2lb. loaves, put into tins, and leave to rise again. When risen sufficiently (it rises more quickly in summer and does not need so much covering as in winter) put into a hot oven and bake 1 hour and 20 minutes.'

WHAT TO DO WITH HONEY.—Paper read by Mrs. C. Schulz (Hon. Secretary).—"Honey is one of Nature's foods that does not spoil and should be more extensively used. Cakes and biscuits made with honey will keep a long time. It is also useful for home remedies. For colds, a hot drink of lemon and honey. For croup, give frequently half a dessertspoon each of olive oil and honey. Oatmeal and honey for the toilet:—Sift a quantity of oatmeal and make into a paste with an equal quantity of honey. Wash hands and face well with water and soap, partly dry, and rub mixture well on to the skin, after a few minutes massage wipe off with sponge or washer and dry thoroughly. Pure honey is equally good for the hands, and 1 teaspoon of honey in a large bowl of water is a good final rinse for the hair.

RECIPES.

Honeycomb Toffee.—4 tablespoons sugar, 2 tablespoons honey or golden syrup, 1teaspoon carbonate soda. Boil sugar and honey for 7 minutes, take off fire, add carbonate soda, mix well and pour into well buttered dish. Use large saucepan.

Honey Cake.—Boil 2lbs. each honey and sugar, $\frac{1}{2}$ cup water, and $\frac{1}{2}$ lb. butter for $\frac{1}{2}$ hour. Pour into a dish and let cool. Then add 6 well-beaten eggs, 3 teaspoons baking powder, $\frac{1}{2}$ packet mixed spice, and flour enough to make a stiff paste. Put in a well greased tin and bake in a hot oven.

Honey Biscuits.—2lbs. each sugar and honey, 1 cup water, $\frac{1}{2}$ lb. lard or butter. Boil together for 10 minutes. Pour into a dish and let cool; add 4 well-beaten eggs, 4 teaspoons carbonate soda, $1\frac{1}{2}$ teaspoons cloves, 4 teaspoons cinnamon, 2 teaspoons allspice, enough flour to roll out. Put almonds on top.

Spiced Honey Nuts.—Cream 2ozs. butter with 2ozs. sugar, add 1 egg (well beaten), $\frac{1}{2}$ cup honey, 6ozs. S.R. flour, a pinch salt, 2 teaspoons cinnamon. Beat thoroughly and blend in 1 cup chopped nuts; drop in teaspoonsful on greased baking sheet, leaving room for spreading.

Honey Crispies.—1 tablespoon honey, cup sugar, 2 tablespoons boiling water, 1 cup flour, $\frac{1}{2}$ cup butter, $\frac{1}{2}$ cup cocoanut, 1 teaspoon carbonate soda, 2 cups rolled oats. Bake 20 minutes.

Honey Jumbles.—Melt $\frac{1}{2}$ lb. butter in $\frac{1}{2}$ lb. honey. Mix 1lb. S.R. flour with $\frac{1}{2}$ lb. sugar; then mix to a smooth paste with melted butter and honey. Smooth into floured fingers, put on a greased oven slide, and bake for 15 minutes.

One Day Yeast.—2 dessertspoons each flour and sugar, 1 dessertspoon honey, 2 potatoes boiled and mashed, 1 teaspoon tartaric acid. Mix together with 2 cups of warm mash. Ready for use in 4 hours.

MUNDALLA (Average annual rainfall, 19.26in.).

March 27th.—Attendance, 16.

The meeting took the form of an exhibition of needlework staged by members of the Branch. (Secretary, Miss L. Kemp.)

NELSHABY (Average annual rainfall, 17in.).

March 1st.—Attendance, 16.

SUMMER SALADS.—Paper read by Mrs. Bain:—"During summer, salads whether fruit or vegetable, are appreciated, and while wholesome and appetising, are easily prepared at a very low cost. Any fruit or vegetable in season has nutritive value, and no meal is complete that does not contain some fresh fruit or vegetables. Raw vegetables, such as carrots, celery, silver beet, turnips, radishes, watercress, cabbages, or young beans were at one time never used in the preparation of a salad, but now they are looked upon as necessary in an up-to-date salad menu. Lettuces are used perhaps more than any other vegetable, but they do not keep fresh for any length of time. Cabbage is an excellent substitute. There are numerous dressings which make a salad more appetising and digestible, but these should never be added until ready to serve. When serving cucumbers or onions never allow to stand any length of time, and always use the juice of the cucumber. Avoid using sugar or vinegar, and displace these with brown sugar, dates, honey, and lemon juice. Olive oil or cream is absolutely necessary so that the salad shall not be indigestible. Peanut butter can be used in place of cream. When onion is used, pour a little boiling water over after it has been finely chopped. This takes away the unpleasant odor. *Tomato Salad.*—Cut up tomatoes, cucumber, and onion very fine, sprinkle with pepper and salt, and add a little lemon juice or vinegar if preferred. *Beetroot Salad.*—Boil a bunch of beetroot until quite soft, then cut into thin slices. Place in a bowl one layer of beetroot and one layer of onion and cucumber or celery until dish is full. This may also be served in cupped lettuce leaves as individual salads. *American Salad.*—Put a cupped lettuce leaf on each server, place in the centre one large tomato, cut downwards in the form of a cross, allowing to open like petals. Intersperse with petals cut from hard boiled eggs. Fill the centre with dressing, garnish with small lettuce leaves standing in the centre; eggs may be omitted and cheese substituted. *Tomato Salad.*—A layer of shredded lettuce, grated onions, sliced tomatoes, and grated cucumber. Repeat until dish is full, garnishing with sliced tomato and lettuce hearts; serve with dressing. *Oyster Salad.*—Place a small cupped leaf on each server. Into this put a mixture of shredded lettuce, grated cucumber, the yolk of a hard boiled egg, a few oysters, 1 tablespoon of dressing to which has been added the liquor from the oysters, finely chopped parsley, and a good sprinkling of cayenne pepper; garnish with lemon. *Madame's Salad.*—1 fresh crisp lettuce finely cut, a few sticks of celery finely chopped, parsley, 1 small grated carrot, a few light leaves from the heart of a young cabbage, and a little grated raw cauliflower. Onions grated may be added if desired

Mix and garnish the top with grated cheese and chopped parsley; serve with dressing. Parsley may be omitted and mint substituted when serving with lamb. *Date and Banana Salad*.—Fill a dish with alternate layers of dates or figs and sliced bananas; squeeze over the juice of $\frac{1}{2}$ a lemon. Cover with whipped cream sweetened. Sprinkle with ground cinnamon. *Cabbage and Carrot Salad*.—Shred the cabbage and place a layer in a salad bowl, then a layer of grated carrot and onion, repeat until dish is full, adding lastly a ring of cabbage and then a ring of carrot until top is covered. Serve with cream and lemon juice which has been salted. *Twin Souls*.—1 orange, 2 bananas (sufficient for four people), peel and pith the orange, cut crosswise into four. Lay a slice of orange on each plate surrounded with laced lettuce. Cut banana in half, lengthways and crossways. Lay 2 pieces on the orange, cover with honey and chopped nuts. Serve with whipped cream. *Dried Fruit Salad*.—1 cup chopped dates, $\frac{1}{2}$ cup each prunes, figs, and raisins and 1 cup dried apricots washed in hot water. A few finely chopped walnuts, 1 apple (grated), a sprinkling of cinnamon and juice of 1 lemon. Serve with whipped cream or junket. *A Natural Dressing*.—4 tablespoons honey, $\frac{1}{2}$ cup cream, 1 teaspoon salt, a sprinkle of pepper, juice of 1 lemon. Mix all thoroughly together. A little mustard may be added if desired and milk with a little butter may be used instead of cream.

O'LOUGHLIN.

March 6th.

JAM MAKING.—Mrs. W. Pfeiffer read the following paper:—“Practically all kinds of fruit are suitable for jam, some may not be quite so useful on their own, but make a good combination with other kinds of fruit. Where the fruit can be picked from the garden it can be used just at the right stage of ripeness, but when the fruit has to be purchased in cases, especially if it has to travel some distance, it has to be carefully picked over. Any soft fruit should be stewed for immediate use. For best results the fruit should be firm, but just ripe, better results are obtained from slightly under-ripe fruit than that which is over-ripe. For the various kinds of fruit there are different methods of preparing. Apricots should be halved and stoned and then weighed; plums likewise, excepting the Damson. Some plums are easy to stone, but some are not, in which case it is perhaps better to allow the fruit to boil without sugar for a while, and try to skim off the stones that come to the surface. But as this method is very tiresome—standing by the fire especially on a hot day—it is preferable if at all possible, to stone the fruit before it goes on the fire. It may take longer to prepare, but it does not tire so much. A sharp, stiff knife is necessary, cut around the fruit, then put both hands on it, and twist the hands in opposite directions, one half is then free and the other is cut as close as possible to the stone with the point of the knife. When accustomed to this method there is less waste than by skimming. These fruits do not need peeling, but any blemishes on the skin should be cut off. With the use of sugar, there are exceptions, but as a general rule, $\frac{1}{2}$ lb. to 1 lb. of fruit is sufficient, but with figs and several of the berry fruits $\frac{1}{2}$ lb. is quite enough. Do not add water to any jam, it usually means longer boiling to make it set, and thus the color is often spoilt. I usually add half the amount of sugar, mix it lightly with the fruit and allow it to stand several hours, because the sugar brings out sufficient moisture to start for boiling. Warm the remaining amount of sugar by standing it in the oven and add it after the jam has boiled about 1 hour. Most fruits with the exception of quinces, apples, and pears should be boiled quickly, the latter need long, slow boiling to get the right color. A reasonably large vessel is more satisfactory than a small one. If the pan is too small the jam cannot be stirred properly, which may cause it to burn. Always stir off the bottom. A board about 3in. wide, tapered on one end to use as a handle, and left wide at the other end and planed to rid it of splinters and well scrubbed, is more satisfactory than a wooden spoon. A child's wooden spade is quite good. While the jam is boiling see that it does not burn, that spoils both flavor and color. It needs most watching until it comes to the boil and more so when nearly done. When the jam has a glassy transparent appearance and bubbles start to come and break into a number of little ones, which is called jellying, it is nearly done. Then it is advisable to take out a little and pour it on to a saucer and allow it to stand in a cool place. If a thin skin has formed on it when it has cooled, then the jam is ready, if however, it is watery, it needs a bit longer boiling. When the jam has cooled off a little, put it into bottles, either pickle jars, or ordinary bottles with the neck cut off. They should be thoroughly clean and dry; this is most essential. If stood in the oven for a while to warm, there is less danger of them cracking when the hot jam is poured in. Fill them right to the brim, as it always contracts a little when it cools. When the jam is well cooled, preferably next day, it should have a nice firm skin. It should be sealed, either paper pasted over it and labelled, or melt pure clean tallow and pour it

over. It should be stored in a cool, dark, and dry place. Where storing space has to be considered, it has to be put into large jars, and perhaps tins. Better results can be obtained from a small lot of jam, say 10lbs. or 12lbs. fruit, than from a much larger quantity. It can be watched more closely, and it does not have to boil so long, thus preserving the color." (Secretary, Mrs. A. Pfeiffer.)

PARRAKIE (Average annual rainfall, 14.64in.).

March 27th.—Attendance, 12.

The meeting took the form of a Question Box. When is the correct time to strike fuchsia cuttings? *Ans.*: One member planted late in August, in a warm position, and was successful. A remedy for keeping moths out of woollens? *Ans.*: Wrap the garments in newspaper, and after cleaning the room spray it with flytox. What is the correct amount of water to add to 12lbs. quinces for jam? *Ans.*: Almost cover the quinces with water. Which is the better for making sponge cakes: Cream of tartar and soda or self-raising flour? *Ans.*: Both give good results; a matter of choice. What is the reason for thick creamy buttermilk? *Ans.*: Butter was made from cream not quite sufficiently matured. (Secretary, Miss J. Halliday.)

PENOLA (Average annual rainfall, 26.06in.).

April 4th.—Attendance, 23.

QUESTION BOX.—What is the best way of cleaning burnt aluminium saucepan? *Ans.*: Put salt in water in saucepan and boil. Tip water out and dry quickly. Leave in sun. What can be done with brown sugar which has become hard and lumpy? *Ans.*: Put in a damp place. A recipe for yellow filling and icing for sponge cake? *Ans.*: Mock cream made with equal parts of butter, sugar, and water. Banana essence is very nice. Will fig jam keep if the figs are gathered after the rain, or will the jam develop mould? *Ans.*: Do not use figs immediately after rain, the jam is likely to ferment. Why is a lesser quantity of rising (especially cream of tartar) used in cakes or rolls containing honey? *Ans.*: Because there is an equivalent acidity in honey. What causes milk puddings to "break" whilst cooking? *Ans.*: A slow oven is essential; a hot oven will always make them break. Stand pudding in dish of water to cook. Recipe for biscuit mixture sometimes used as pastry? *Ans.*: 2 cups flour, $\frac{1}{2}$ lb. butter, 1 cup sugar, 1 teaspoon cream of tartar, $\frac{1}{2}$ lb. carbonate of soda, 1 egg, 1 tablespoon milk. How to make scones? *Ans.*: 1lb. flour, 2 teaspoons cream of tartar, 1 carbonate of soda, pinch of salt. A teaspoon icing sugar and the addition of cream improves the flavour. Some people prefer to pat dough into position for cutting with the hands, others always roll the dough. How to keep flowers fresh in wreaths, make-ups, &c.? *Ans.*: Pick flowers in the cool of the evening or early morning, and handle carefully to avoid bruising. Place in deep water with an aspro until needed. When working wreath do not bruise flowers, and never work the flowers dry. After completing work spray well, back and front. Pack carefully, and keep in an air-tight box. How to salt mutton? *Ans.*: Mix the following and rub well into the meat, turn meat every second day, and apply more of the mixture:—2 cups salt, $\frac{1}{2}$ cup sugar, 2 teaspoons carbonate of soda, 1 teaspoon saltpetre. (Secretary, Mrs. F. Kidman.)

RENDELSHAM.

March 7th.—Attendance, 7.

SALMON RISsoles.—Recipe supplied by Mrs. Smith:—1 tin salmon (with juice drained off), about 3 cups finely mashed potatoes, 1 tablespoon butter, salt and pepper to taste, 1 onion grated or chopped finely, 1 handful chopped parsley, 1 egg. Method: Shred salmon, whip butter, pepper, and salt in the mashed potato, then mix all ingredients thoroughly together, form into rissoles, roll in flour or finely crushed crumbs. Fry a golden brown in butter. (Secretary, Mrs. Andrews.)

April 4th.—Attendance, 12.

SAVOURIES FOR BREAKFAST AND LUNCHEON.—Paper read by Mrs. M. McArthur:—"Breakfast is usually a hurried and quickly prepared meal. The following are some tasty and quickly prepared savouries. Toasts can be served in a variety of ways which are both wholesome and easily digested. The proper foundation for all toasts is twice baked or dry toast. *French Toast*.—2 or 3 eggs, add as much milk as will

do to soak enough bread sliced for the family. Beat eggs and milk, add salt and pepper to taste. Dip bread and fry in boiling fat or butter until a golden brown. *A Tasty Savoury*.—Allow a slice of toast to each person, place some cheese on top, some fried bacon, and a little of fried tomato. Place in oven for a few minutes and serve hot. *Omelette*.—4 eggs, a little butter, salt and pepper, chopped parsley and meat. Beat eggs, mix all together and fry a golden brown. *Scrambled Eggs and Ham*.—Mince ham and fry for a few minutes, then add lightly beaten eggs and a little milk, salt and pepper to taste. *Rossos*.—Cut any cooked meat into very small pieces, break an egg into a basin, add salt and pepper and 1 cup of flour. Mix well with $\frac{1}{2}$ cup milk, then add cut-up meat, mix all together and drop spoonful into pan of hot fat and fry. Midday meal is usually a light luncheon, as most people have their dinner at night. *Beef Olives*.—Cut 2 or 3 pieces of steak, make a stuffing, and roll it in the steak; tie with string or skewer together. Simmer in water until tender. A little gravy in roast meat improves the flavour. *Fricassed Brains*.—Two sets of sheep's brains, 1 egg, a little parsley, butter, pepper and salt. Soak brains in salt and water for 20 minutes. Wash well and remove any skin; put into saucepan and simmer for five minutes. Drain and beat with a fork; add egg, pepper, salt, butter, and parsley. Fry or stir over fire until thick. Serve hot on toast or cold in sandwiches. *Cheese Straws*.—3ozs. each flour, butter, and cheese, yolk of 1 egg, squeeze of lemon juice, a little cayenne and pinch of salt. Sift flour, add butter and grated cheese; mix yolk of egg and lemon juice; work all into a lump, then roll out and cut into biscuits and bake from 5 to 10 minutes, until a pale straw colour. *Savoury Puffs*.—Make a light scone dough, roll out thin, cut into squares, put 1 tablespoon of savoury mince on each square and press together like turnovers; fry in boiling fat. Serve very hot and garnish with parsley."

MUSHROOM KETCHUP (Mrs. Sly).—Break 6lbs. mushrooms into an earthenware jar and sprinkle with $\frac{1}{2}$ lb. salt. Put in a cool oven or near a fire for 12 hours to extract the juice. Then strain and measure syrup. Allow it to settle and boil for $\frac{1}{2}$ hour. To each quart of syrup add $\frac{1}{2}$ oz. all spice, $\frac{1}{2}$ oz. whole ginger (bruised), 2 blades of mace, 1oz. peppercorns. Boil quickly for $\frac{1}{2}$ hour. Strain and cool before bottling. Cork well and seal. Try and gather dry mushrooms to ensure long keeping. (Secretary, Mrs. E. Andrews.)

SADDLEWORTH (Average annual rainfall, 19.55in.).

April 3rd.—Attendance, 10.

THE USES OF GRAPES.—Paper read by Mrs. Coleman:—"Grapes are such a beautiful and wholesome fruit and the soil and climate of our State is so well adapted to the growth of the grape that much more use should be made of this fruit by the people of South Australia. There is a growing demand for the dried products of the vine, no doubt owing to the publicity campaign of the Dried Fruits Association. We should do all we can by a more liberal use of raisins, sultanas, and currants in our cooking to increase the demand, and so help the vine-growers. From the 1931-1932 'Commonwealth Year Book':—Export value of raisins and currants, £3,034,304—about one-quarter the value of wheat exported, but nearly double that of wine. From 1933 'Production Bulletin' the following values are of interest:—From 1930-1933 from all States—Grapes for table use, £289,719; dried vine fruits, £2,621,000; grapes for wine, £585,523. These figures show the importance of the vine-growing industry to the progress of the Commonwealth and our State in particular. For a number of years I have preserved grape juice for use as a drink during summer. A variety of blends can be made. The Muscatel grape I consider the best flavour. The Black Muscat has a red colour, and looks more attractive. The following is a good recipe:—Wash grapes and mash slightly; beat in a pan or double boiler until seeds are free from pulp and mixture is soft. Turn into fine strainer or jelly-bag and let drip. Fill juice into bottles and sterilize as in preserving fruit, and seal, using good new corks, and cover with wax, or use Fowler's fruit juice bottles with china stoppers, ring, and spring. To make a sweeter mixture: After straining, add 1 cup of sugar to 4 cups of juice, heat again, fill bottles, and cork immediately. To use: Take $\frac{1}{2}$ tumbler of juice and add cold or ice water. Lemonade or lemon juice is also an improvement. *To make Grape Cup*—Use about 1 cup of grape juice, fresh or bottled, juice of 2 lemons, 2 passion fruit, sugar to taste, about 1 pint of water or aerated water, slices of lemon to float. Ice. This is very good for use at evening parties. 'The Ideal Recipe Book,' price 6d., edited by Emily Stanton, contains recipes for use of grapes, raisins, &c. I can recommend them, as I have them in constant use. Grape juice is especially good for invalids as part of their diet; it is so easily assimilated. Raisins have a high energising value, and are especially useful in the diet for children. There are many ways they can be used at every meal. Raisins with cereals for breakfast, raisin and sago plum puddings or

raisin tarts for lunch or dinner, raisin and lemon mixture for afternoon tea sandwiches, raisin bread and cakes for tea. The following table shows the value of raisins in energising power:—1lb. of raisins is equal to 1½lbs. of beef, 6lbs. of apples, 5lbs. of bananas, 4½lbs. of potatoes, 4lbs. of milk, 20 eggs." (Secretary, Miss G. Frost.)

TANTANOOLA.

March 28th.—Attendance, 13.

SWEETS MAKING.—Mrs. Considine read the following paper:—"Have all ingredients, weights, measures, and dishes ready at hand. I always use a hollowware saucepan. *French Delight.*—Soak 2ozs. gelatine in 1 cup of cold water for ½ an hour, boil 2lbs. sugar and 1 cup water for 15 minutes. Put in the gelatine and boil for 35 minutes. Add a few pieces of citric acid, and flavour with ½ teaspoon of essence of lemon. Colour half with cochineal and pour on dishes dipped in water. Cut up when set and roll in icing sugar. *Date Creams.*—2 cups sugar, ½ cup milk, small piece of butter. Boil all slowly for 7 minutes. Add pinch of cream of tartar. Take off fire, place pan in basin of water, and beat mixture to a cream. Have dates all stoned and put portion of mixture into each. *Cocoanut Ice.*—Take 2 cups sugar, ¾ cup milk; boil 5 minutes, then add 3 tablespoons cocoanut and boil 4 minutes. A small tablespoon of butter and pinch of cream of tartar or citric acid can be added. Beat until thick, colour half pink. Pour into buttered dish; cut in squares. *Walnut Creams.*—Make paste same as above. Halve walnuts and place portion of mixture between each. Almond creams can be made the same way. *Ginger Balls.*—Make paste same as for date creams: flavour with ginger essence, colour to suit; take small pieces of preserved ginger and roll in paste. *Acid Drops.*—Take 1 cup water, 1lb. loaf sugar, 1 tablespoon vinegar, ½oz. tartaric acid, essence of lemon. Put sugar, vinegar, and water into a saucepan and boil until it becomes brittle. Melt the tartaric acid in a little hot water, add essence of lemon. Mix well, drop into the saucepan, and stir. Turn it out and cut into small squares and roll." (Secretary, Mrs. Telfer.)

TAPLAN, March 21st.

WOOL AND ITS USES.—Mrs. Hodge read the following paper:—"Wool for knitting is now very cheap, and 4-ply wool at 4½d. per skein makes nice jumpers, cardigans, &c., for school girls, and is cheaper than other woollen materials, because only 8 skeins are required, or even less for smaller girls. This would cost 3s., and if the girls are able to knit, they can quite easily make jumpers themselves with an occasional helping hand. I start jumpers on No. 11 needles and knit 1 purl, 1 plain for the band about 2½in., and then change to No. 9 bone needles. This works out at a tension of 8 stitches to the inch. It is easy to work out a larger size jumper on this scale, plain knitting. For woman's size—36in. bust measurement—I use 8 skeins 4-ply, less of 3-ply, and as the cost is so small, two or more jumpers can be made; they are comfortable and can be worn on most occasions. Any wool that is left over can be used for knitting cosies, bows for dresses, collars and cuffs; in bright and contrasting colors they will brighten a dark woollen dress. Men's and boys' hand-knitted socks are much more comfortable, and wear longer than those purchased in stores. The former can be re-footed when the feet and heels wear out, which saves a lot of knitting and wool."

FARM HOME SURROUNDINGS.—Paper read by Mrs. Stewart:—"How often when driving along a road does one hear the remark: "There's a lovely home." On closer examination the house itself is found to be a very ordinary structure. Why, then, the exclamation? Because the surroundings were prettily laid out and cared for as if someone enjoyed living in the home. Something fresh and green is what our senses crave in this hot, dry and dusty district. Trees first; Two rings of them around the home, of course a good distance away. Sugar gums are favored, for after trying half a dozen different kinds of trees I find the gums stand the climate much better than other varieties. The white cedar does quite well, as does the kurrajong, but both grow more slowly. Surround the home with trees, and no matter how poor or how grand the house, it will look like a home. The residence that looks, and is, a real home is the desire of every woman. During these days of depression it may not be possible to improve the actual house or renew or redecorate the interior. The shabby linoleum, the faded woodwork, the lessening crockery, and the emptying linen press are too depressing, so let us see what we can do to make the home look as if we are prosperous. Water is still available. The gums around the house help to break the wind; but if some breaks of hophbush are erected the work of making a garden will be more satisfactory. If possible have the flower garden opposite the kitchen window, or somewhere where you can constantly see it as you go in and out about your work. No work is dull if in the midst you are cheered by the sight of a

gay garden. The vegetable patch, too, must not be very distant from the house because of watering. A trellis of vines is an acquisition to any farm home. Fruit trees are a luxury rather than a paying proposition. They take so much water to do justice to themselves. The apricot, peach, nectarine, and citrus trees give good returns. Be very careful not to plant the fruit trees too close to the flower garden or the useful vegetables. At first, while the trees are quite young, vegetables can quite well be grown amongst them; but soon the trees will take all the moisture. A small lawn will give endless pleasure to children and adults if placed where the shade of a tree falls upon it. Have you a shady spot for pot plants? If so, be sure and utilise it for the growing of ferns, &c. Sword ferns do particularly well if there is a sheltered corner facing the east. On the hottest day this corner will always look fresh and cool. If it is possible, have neat fences, paths, and breaks. This will add greatly to the appearance of the home. Farmers cannot be expected to do these things all at once; but little by little the surroundings of the home may be improved. Not only from an aesthetic point of view are we repaid for our labors, when the time for selling comes a prospective buyer will be more favorably impressed by happily laid-out grounds around the homestead than if there is just the bare house. Since we live in this district let us make the best of our one big favor—the water. Plant and tend until one is closed in from the dry burnt land outside by a bower of greenery." (Secretary, Mrs. Flynn.)

WARRAMBOO.

April 10th.—Attendance, 12.

EVERY DAY HAPPENINGS.—Answers supplied by members and visitors. Raw or boiled potato for yeast in summer? *Ans.*: Boiled potato preferred (Mrs. Chilman). Washing bread tins after baking? *Ans.*: Unnecessary to wash them (Mrs. Daniel). Best pastry for meat pies and pasties? *Ans.*: Short pastry with rising meat not cooked previously (Mrs. Dolphin). Which is better, to warm the butter or sugar for biscuits? *Ans.*: Warm the butter in cold weather (Mrs. Adams). Which is preferable for sponges, stale eggs or fresh? *Ans.*: Not too fresh; eggs must be cold (Mrs. Murphy). Why do custards go watery when baked? *Ans.*: Too much sugar, separated milk, too hot oven (Mrs. J. Sampson). The quickest cure for insect bites? *Ans.*: Bathe with peroxide, apply Doan's ointment (Mrs. Mitchell). First remedy for colds and coughs? *Ans.*: Asperin and hot lemon; irritating cough, honey and warm milk (Mrs. G. Simmons). To keep silverfish and moths from clothes. *Ans.*: Camphor balls and flytox (Miss Hampel); other suggestions—Epsom salts sprinkled around, and turps, pepper, and newspaper. Ways of cleaning grease from clothing and hats, &c.? *Ans.*: Petrol, eucalyptus, gall soap (Miss Steer); removing ink and pencil marks, glycerine. Feeding young chicks? *Ans.*: Grind wheat through mincer (Miss Chilman). (Secretary, Mrs. A. Steer.)

WASLEYS.

April 5th.—Attendance, 37.

The meeting took the form of a dahlia show, and many fine blooms were exhibited. The prize winners for six dahlias were—Mrs. M. Richter first, Mrs. C. Marshall second. Best collection of dahlias—Mrs. M. Richter first, Mrs. C. Marshall second. Mr. and Mrs. P. H. Gwynne, of Gawler, were the adjudicators. Mr. Gwynne gave a very interesting talk on "Flower Culture," and answered questions. (Hon. Secretary, Miss J. Braun.)

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Bureau Conferences.

District Conferences will be held as follows:—

Eyre's Peninsula (West), at Ceduna, Wednesday, July 4th, A. R. Maguire, Mudamuckla (Secretary).

Upper North, at Wilmington, Wednesday, July 18th, Chas. Cole (Secretary).

Murray Lands (West), at Karoonda (Nunkeri Branch), Tuesday, July 31st, E. R. Peltz, Nunkeri (Secretary).

Southern, at Strathalbyn, Thursday, August 16th, F. W. Allison (Secretary).

Hills, at Coromandel Valley (Blackwood Branch), Thursday, August 23rd, H. Goldsack, Coromandel Valley (Secretary).

Eyre's Peninsula (Southern), at Yeelanna, Wednesday, September 5th, R. B. Wilson (Secretary).

Eyre's Peninsula (Central), at Kyancutta, Friday, September 7th, E. A. Kelly (Secretary).

Pinnaroo Line, at Pinnaroo (Parilla Well Branch), Tuesday, September 18th, E. C. Slater, Pinnaroo (Secretary).

Murray Lands (East), at Caliph, Thursday, September 20th, W. H. Todd (Secretary).

Fruit (Non-irrigated Districts), at Balhannah, Tuesday, November 6th, C. G. Grasby (Secretary).

In each case the Conference will commence at 10.30 a.m. Members of Branches are invited to submit papers and questions for the agenda.

Agricultural Shows.

We have been advised by Secretaries of Agricultural Show Societies that their shows will be held as follows:—

Maitland, Wednesday, September 26th.

Denial Bay, Friday, September 28th.

Jamestown, Wednesday, October 10th.

Loxton, Wednesday, October 10th.

Burra, Wednesday, October 24th.

Minlaton, Wednesday, October 24th.

Murray Bridge, Thursday, October 25th.

Woodside, Saturday, November 3rd.

Pruning Competitions.

River Murray—Mypolonga (date to be fixed); Cadell, June 26th; Waikerie, June 27th; Moorook, June 28th; Barmora, June 29th; Berri, July 3rd; Renmark, July 4th; and the championship at Berri, July 5th.

Noxious Weed.

The weed known as Horny Thorn Apple (*Datura tatula*) has been declared a noxious weed throughout the whole of the State, under the Noxious Weeds Act, 1931. A description of this plant will appear in a subsequent issue of this *Journal* as part of the series of articles by Mr. G. H. Clarke.

Suppression of Weeds by Fertilizers and Chemicals.

The literature giving information on the use of fertilizers is very extensive, as is that dealing with weed destruction by chemical means, and experiment and research covering both is of world-wide importance. A valuable effect of fertilizers is the

The 'riskier' the road the more you need **Perdriau**

When you get off the beaten track and head for some secluded spot in the hills, there's peace of mind in knowing that your Perdriau Tyres will stand up to the worst roads you may meet.

The **double-toughened** Perdriau tread takes them as they come—bitumen, gravel, stone or rutted bush tracks—and grips more surely and wears more slowly all the time.

You can buy **double-tough** Perdriau Tyres now at the lowest prices ever known. Get your dealer's quote.

Product of the Dunlop Perdriau organisation which *makes and sells more tyres than any other manufacturer in Australia*

Perdriau *double tough* **TYRES**

fact that they enable crops to grow vigorously and overcome weeds. Towards the end of last century, spraying with copper sulphate to kill charlock and wild radish was introduced in France, and soon became widespread in England and elsewhere. At the present time the use of a solution of sulphuric acid is rapidly becoming a recognised means of destroying various annual weeds in cereal crops, as is the fertilizer cyanamide, while chlorates may in the future grow in importance for the destruction of certain weeds in some circumstances. Mr. H. C. Long, of the Ministry of Agriculture of England, has prepared a simple and concise account of the subject in a brochure entitled "The Suppression of Weeds by Fertilizers and Chemicals." He has had the benefit of the assistance of Dr. Winifred Brechley, of Rothamsted Experimental Station, and the subject is introduced by a foreword from the pen of Sir Daniel Hall. The booklet extends to 57 pages, together with 17 photographic illustrations and five line drawings. It may be obtained from the author at "The Birkins," Orchard Road, Hook, Surbiton; price 2s. net (by post 2s. 2d.).

Poisoning Trees.

Inquiries have been received seeking information on the best means of poisoning large trees. At our request a paper on this subject was written by Mr. F. R. Dinning, who has had a wide experience in the work at Mundulla, and the article will be found on page 1309 of the May issue.

Declared Noxious Weeds.

The following are declared noxious weeds throughout the whole of South Australia under the First Schedule of the Noxious Weeds Act, 1931:—

- Cotton Bush { (*Asclepias fruticosa*).
(*Asclepias rotundifolia*).
- Wild Onion (*Asphodelus fistulosus*).
- Saffron Thistle (*Carthamus lanatus*).
- Innocent Weed (*Cenchrus tribuloides*).
- Purple Star Thistle (*Centaurea calotritra*).
- Yellow Cockspur (*Centaurea solstitialis*).
- Canada Thistle (*Cirsium arvense*).
- Hemlock (*Conium maculatum*).
- Dodder (*Cuscuta* spp.).
- Horny Thorn Apple (*Datura tatula*).
- Thorn Apple (*Datura stramonium*).
- False Caper (*Euphorbia terracina*).
- Cape Tulip { (*Homeria dollina*).
(*Homeria miniata*).
- St. John's Wort (*Hypericum perforatum*).
- Horehound (*Marrubium vulgare*).
- Black Eyed Susan (*Ornithogalum thyrsoides*).
- Dyer's Weed (Weld) (*Reseda luteola*).
- Buffalo Burr (*Solanum rostratum*).
- Apple of Sodom (*Solanum sodomaeum*).
- Californian Burr (*Xanthium californicum*).
- Bathurst Burr (*Xanthium spinosum*).

The Weeds under the Second Schedule are:—

White Goosefoot ("Fat Hen") (*Chenopodium album*)—City of Adelaide and Waikerie Irrigation Area only.

Fennel (*Foeniculum vulgare*)—Municipality of Mount Gambier only.

Variegated Thistle (*Silybum marianum*)—Municipality of Mount Gambier only.

Hoary Cress (*Lepidium draba*)—District Council of Tatiara only.

African Boxthorn (*Lycium ferocissimum*)—Declared a noxious weed for the whole of the State, except where grown as a hedge on the 17th March, 1932, and kept trimmed to a width not exceeding 4ft. 6in. in any part and a height not exceeding 7ft.

VETERINARY INQUIRIES.

[*Replies supplied by Veterinary Officers of the Stock and Brands Department.*]

Ellston has cow on first calf. One teat has lumps in it, and gives milk tinged with blood.

Reply—The presence of blood in the milk is due to the rupture of a small blood-vessel in the lining of the teat duct. The occurrence of such a haemorrhage would undoubtedly be assisted by the presence in the teat of the lumps you report. These are small growths or tumours caused by an infection of the quarter with a mild chronic form of mammitis. There is no satisfactory treatment for the removal of these lumps, though their removal by operation may be attempted by a properly qualified veterinary surgeon. The only treatment you can adopt, when the blood is found in the milk, is to milk the quarter out as gently as possible three or four times a day for a few days, so as to allow the ruptured blood vessel every chance to heal up again.

Mannum reports dog with undue proportion of the white of the eye showing, and has difficulty in seeing any object.

Reply—Keep the dog quiet, and feed on light nutritious diet, such as meat and vegetable soup, finely minced raw red meat, stale dry bread. Keep the animal's bowels in regular order by giving once weekly a dose of castor oil, 2 tablespoons; olive oil, 2 tablespoons; calomel, 1 grain—all mixed together and given as one drench. Three drops of Fowler's solution of arsenic should also be given in a little milk, night and morning for a fortnight. Then discontinue its administration for a fortnight, and repeat the course again.

Pinnaroo reports yearling colt with a cut under and in the corner of the eye. The wound is healing, but the eye has a blue skin over it.

Reply—If possible, keep the animal in some shady position where the eye is protected from the direct sunlight. Clean any mattery discharge by bathing with warm boracic lotion, and three or four times daily put a few drops of the following lotion into the eye sac and hold the lids closed for a minute until the lotion becomes distributed all over the front of the eyeball:—Zinc sulphate, 4 grs.; acid boric, 4 grs.; boiled or distilled water, 2 tablespoons.

Milang Agricultural Bureau reports cow with weeping sores and scabs on all legs.

Reply—It is impossible to definitely diagnose the nature of the trouble without seeing the animal, but the condition is probably due to infection of slight skin wounds, such as scratches, &c., with the *Bacillus Necrophorus* (or *Necrosis Bacillus*), which germ is a common inhabitant of soils. This condition usually responds readily to treatment by removing the scabs after softening them by bathing with a warm antiseptic solution, and then dressing the raw sores with either 3 to 5 per cent. solution of milk oil fluid or 3 to 5 per cent. carbolized vaseline.

The condition as a rule is not highly contagious, and the only precaution to take is to isolate the animal until recovery. Occasionally it may happen that several members of a herd may become affected at or about the same time, in which case it is advisable after separating the affected from the non-affected animals to move the latter to a fresh pasture.

Pata forwards flies for identification.

Reply—The specimens were submitted to the Museum Entomologist, Mr. Walmesley, who advised as follows:—

Both flies belong to the same group, the larger one being the common botfly (*Gastrophilus Equi*), which deposits its eggs anywhere on the horse, and the smaller one being the *Gastrophilus Veterinus* (*G. Nasalis*), which deposits its eggs around jaw and head.

In both cases the eggs have to be swallowed, and in the stomach they develop into the maggot or larval stage. They remain attached to the stomach near entrance to small intestine all winter, and in late spring are passed out in the faeces. They then burrow into the ground, where they remain from 3-5 weeks, when the winged fly emerges. Bots, contrary to popular opinion, do not cause the damage that is attributed to them, but they occasionally cause death through obstructing the passage of food, etc., into the intestine.

Caliph Agricultural Bureau reports death of three horses. Post-mortem showed heavy infestation of bots, which were suspected of causing the deaths.

Reply—In my opinion "bots" were not the cause of the death of the horses. At this time of the year digestive disturbances in horses are common. They have been "turned out" and on "low rations." When brought in they are usually in poor condition, and as they are usually wanted for work at once, are put on to better feed. Their poor condition, the sudden change of feed, especially if it is given in large amounts frequently leads to digestive troubles, especially in districts where "sand" is common.

The remedy is to give horses "turned out" a little supplementary feed. When they are brought in, give a bran mash for 2-3 days and gradually change on to new feed.

To prevent botfly strike, clip hair over areas liable to strike and apply following dressing daily:—Creosote, 1 part; oil of turpentine, 6 parts; raw linseed oil, 20 parts.

Morgan asks: (1) Cause and treatment of spavin, and (2) whether wheat can be fed to a cow without causing bloat.

Replies—(1) *Re "Spavin."*—The predisposing cause of this condition is faulty conformation of the hock joint. The actual or exciting causes are sprain and concussion. The result of treatment for alleviating the lameness caused by this condition is always problematic, as it depends on many factors, such as the position of the spavin on the joint, temperament of animal, nature of work to be performed, presence of faulty conformation, &c. Treatment consists of rest and either the application of a 1 to 8 "Red" blister (obtainable from any chemist) over the site of the spavin or "firing." This latter treatment can be given only by a qualified veterinary surgeon.

(2) *Re Cow "Bloating."*—Wheat is a feed that is very prone to induce bloating in stock unless it is fed in limited quantities only, the stock have been gradually accustomed to it and care is taken not to give it to them when they are empty and hungry, so that they "bolt" it. Take the precaution of always taking the edge off the cow's appetite by first feeding it a little hay, prior to giving the wheat and chaff feed, and the tendency to "bloating" will be very greatly reduced.

Strathalbyn asks if it is advisable to drench ewes with bluestone that are due to lamb in two months' time.

Reply—If the ewes are showing signs of parasitic infestation, it would be advisable to drench them now, and provided they are carefully handled, this treatment could be carried out quite safely. Otherwise, if they appear in good health, drenching should be left over until after lambing. Then it might be possible for you to drench the ewes once at the same time as you are marking the lambs. Regular monthly drenchings of both the ewes and lambs could be instituted from October or early November onward until the following April or May.

Agricultural Bureau, Elbow Hill, asks treatment for removal of worms in horses.

Reply—A routine treatment is to starve the animal for 24 hours and then give the following drench:—Raw linseed oil, 1-2 pints; oil of turpentine, 2oz. Shake well before administering, and do not feed the horse for two hours after drenching. Procure a 1lb. bottle of Fowler's solution of arsenic and give 1 tablespoon night and morning sprinkled on the feed until the bottle is finished, and then repeat the oil and turpentine drench.

Worms can largely be prevented by seeing that the horses do not eat food contaminated with manure, and drink water that has been polluted with animal droppings. Stable yards and stables should be cleaned regularly, and manure piled up in heaps in a compact mass, or carted out and spread on land which is to be used for cropping purposes.

If from dams, the water used for drenching should be always taken from a trough. It is pointed out that trough water is often known to contain numerous small red bodies about $\frac{1}{16}$ in. to $\frac{1}{8}$ in. in length, which are often mistaken for "blood worms," but they are the larval form of an insect which, as an adult, is like a mosquito. These larvae differ from the "blood worms" in appearance, in that the body has distinct constrictions and a beadlike appearance, whereas in "blood worms" the body is uniformly plain and round.

Agricultural Bureau, Yurgo, asks treatment for pink eye in sheep.

Reply—Pink eye in sheep is due to a germ infection and the disease is usually introduced with bought sheep. Symptoms—Spreads rapidly through flock, and causes rapid loss of condition. Eyes watery, lining membrane red; later the affected eye goes whitish in colour, and the surface may ulcerate and rupture.

Isolate all affected sheep (when handling sheep disinfect hands after each one to avoid spreading infection) and put in a suitable and handy spot. (The ideal is a small paddock with plenty of shade and water.) Feed by hand. Put a few drops of 2 per cent. solution of zinc sulphate into the eye daily for a few days. (To make solution, dissolve 3 drams of zinc sulphate in 1 pint of boiled water.)

Tarcowie reports mare swollen leg of long standing. Recently discharging from just above fetlock. Leg is very stiff.

Reply—The animal is suffering from lymphangitis, an inflammatory oedema of the leg. She should be kept in a small yard where she can take quiet voluntary exercise. A dose of physic should be given and the animal kept on light restricted diet, such as mash or greenfeed. A careful search of the affected limb should be made for any wounds, and these dressed with antiseptics. The leg should be treated with hot fomentations applied by means of a large piece of flannel or blanket dipped in real hot water and wrung out almost dry. This latter point is essential, otherwise the skin of the leg may be injured by scalding. These daily fomentations should be followed by massage in an upward direction and the limb kept bandaged between times from the foot up to above the hock. When the acute stage is passed, the animal should be given 15-20 minutes walking two or three times daily.

Once this trouble has occurred in a limb, it is very liable to recur again, and after each succeeding attack the limb shows less tendency to return to normal size, becoming more or less chronically enlarged. An animal affected chronically with this disease should be kept at reasonable work as constantly as possible, and when being spelled should be kept in an open yard instead of being stabled.

AGRICULTURAL EDUCATION.

[*An address broadcast through 5 CL, Adelaide, by DR. A. R. CALLAGHAN, Principal, Roseworthy Agricultural College.*]

With the limited time at my disposal I do not purpose covering all the ramifications and perplexities which confront the educationalist in dealing with the problem of industrial education. In any case, it would be presumptuous on my part to obtrude my opinion on such an important and specialised matter. What I do purpose doing, however, is to outline what in my opinion, as an agriculturalist rather than an educationalist, is considered to be some of the essential fundamentals in the training of young men in agriculture.

Before proceeding with any educational programme one must have some definite idea in mind respecting the immediate object and ultimate result.

At the outset it must be fully realised that experience is the greatest teacher of all, and in no phase of life can experience be truly transferred. So that no school or college system can ever succeed in moulding experienced farmers, or experienced agriculturalists, but what it can do is to inculcate a proper sense of values, foster a keen sense of observation, and develop a reasoning, clear-thinking mind, thereby making the subject of agriculture live from the very beginning. In other words, early educational efforts in agriculture should be directed towards the training of young men to be agriculturally minded, that is, to think along agricultural lines and to be able to parse and analyse the problems, failures, and successes of the man on the land. With such a training any young man can approach the practical work of the farm with the knowledge that the essential experience, which is the precursor of success, will be fully taken advantage of, and bear good fruit earlier than would otherwise be possible. One of the gravest mistakes, to my mind, is to begin specialisation too early. A sound fundamental education is just as essential for success in agricultural pursuits as it is for success in any other profession. Without a good working education a lad cannot ever hope to grapple with the underlying sciences and principles of agriculture. His mind is not sufficiently well trained to understand the work that is involved when specialisation does begin, nor has he acquired that thinking habit so essential to the proper interpretation of what he is learning and doing. It almost goes without saying, that the higher the degree of intelligence, and the sounder the educational foundation, the better chance there is of making a sound agriculturalist. It is a grave fallacy for parents to conclude that, because their son has failed to qualify for other professions, his only chance of success is to go on the land.

Agriculture involves scientific as well as business principles; it involves the application of some of the most profound branches of human knowledge, and above all, requires a clear, commonsense attitude; consequently, to be truly successful, there is need for a sound educational background combined with intelligence. With the crowding of other professions it is very agreeable and heartening to note the increased number of boys of sound education and of high intellectual calibre who are entering Roseworthy Agricultural College. They have chosen agriculture as the business of their lives, and with their minds adequately equipped in the first place the task of training them along more specialised lines is made both easier and more pleasurable.

The knowledge of the world, and matters of science particularly, both natural and physical, has grown stupendously; so much so that education has of necessity developed along mundane and utilitarian lines, and the strictly scholarly aims have to a large extent been modified to meet the times. Education must keep in step with time, for every boy has eventually to plunge into the whirlpool of real living, and his education very largely determines whether he will sink, swim, or float aimlessly about. This encumbers upon our system the necessity to specialise,

and one of the lines of specialisation most important to the future of Australia as a whole, and South Australia in particular, is that of agricultural education.

Now assuming that a reasonably sound educational background, involving the three "R's" well done, has been received, introductory work of a foundational nature should begin the specialisation, and this can best commence while the boy is still at the secondary school. Elementary chemistry, physics, and botany might well enter into this foundational work, but rather than attempt the lot and confuse the young mind, I consider it preferable to take one or two, and make sure that what is taught, is taught, not with the idea of assimilating a series of cold facts, which are meaningless, but with the idea of teaching living facts and principles which are of definite applicability and use in life.

A boy leaving school and entering an agricultural college, such as Roseworthy, with a sound introductory schooling of this sort, has a decided advantage over the boy whose general education has been neglected or is incomplete, merely because he has been gleaning something of what the College is to teach him in detail later on. From this it should not be concluded that I am against the teaching of agriculture and kindred subjects at agricultural high schools. These institutions serve a wonderful purpose, especially for country children, but for boys who anticipate going further by taking a course at Roseworthy, greater time might, I consider—speaking again as an agriculturalist rather than an educationalist—be given to matters of general education and introductory work on the physical and natural sciences, than to subjects of a purely agricultural nature, which demand more practical than theoretical teaching.

I am firmly convinced that no system of agricultural education is complete, or even possible, without some intimate form of practical work. The very basis of agriculture and livestock husbandry is practical. What is more, it all involves actual labour, yet underlying this are the intellectual aspects; these aspire to make the efforts involved more productive, more profitable, and last but not least, more enjoyable. My conclusion from this is that any college which neglects the practical and everyday tasks involved in farming, and which neglects to portray by practical example what it portends to teach, is nothing more or less than a machine for cramming cold, meaningless, and indigestible facts likely to ruin the digestion of its students.

Whatever the branch of education, be it agricultural or not, the teaching of things which may be mechanically memorised, just as mechanically transcribed to examination papers, and in many cases automatically forgotten, is defeating the objects of true education. To ring true, facts must be shown to be more than mere words; they must be interpreted to reveal their worth, their practical application or utility, or at least to be clearly understood as something really worth while knowing, for the sake of knowledge itself, and not for the purpose of passing an examination. And so it is that all agricultural colleges deserving of the name are so situated as to be in a position to practise the subjects which they aim at teaching. Students are thereby afforded the opportunities, not only of following the practical procedure adopted, but also of actually doing the work. The theoretical training which accompanies, and is an integral part of the practical operations, teaches them to appreciate the why's and wherefore's of certain procedure, and enables them to take an intelligent, thinking interest in their work. There is a world of difference in knowing what to do and how to do it, and ambitious as it may sound, the objects of Roseworthy are to teach both; but without careful attention to practical work, the "how to do it" part would obviously not even receive its introduction. The attainment of sufficient agricultural knowledge and training to enable students to think along the right lines is a big step in the right direction, and although experience must mellow the early training, when such experience is superimposed on a sound agricultural education, it is not only more profitable and lasting, but it is also more satisfying and liveable.

LAND SETTLEMENT ACTIVITIES OF THE EMPLOYMENT PROMOTION COUNCIL.

[By W. J. SPAFFORD, Chairman of Land Settlement Committee.]

After prompting by representatives of various organisations interested in attempts to overcome some of the unemployment prevalent at the time, the Government of the day created the Employment Promotion Council, and promised to subsidise £ for £ up to £25,000 funds raised by the Council by public subscription. After careful consideration Members of the Council decided that the time was inopportune to hope to obtain a large sum of money from the general public on an appeal, but they were saved from their dilemma by a grant made by the Commonwealth Government of £25,000, the conditions of the grant being:—

1. That the State subsidise the grant £ for £.
2. That £20,000 be used for land settlement and £5,000 for mining.
3. That the State subsidy be used for the same purpose as the grant, and in the same proportions.

The State Government accepted the conditions, and the Employment Promotion Council immediately functioned in providing work connected with mining and in placing men on the land.

To facilitate the work of the Council the Honourable Minister of Employment and Industry made provision for Committees to work under the Council, and at present Committees on Finance, Mining, Land Settlement, and Publicity do the spade work, and submit recommendations for the consideration of the full Council.

THE COUNCIL.

The Employment Promotion Council was constituted on September 5th, 1932, and consisted of the following members, each representing an organisation of some kind:—

The Lord Mayor of Adelaide.

The Council of Churches (Rev. B. E. C. Tuck and Rev. Wm. Hawke—the latter was replaced by Mr. L. V. M. Leal).

The Lord Bishop of Adelaide (represented by Rev. Canon Bleby).

The Archbishop of Adelaide (represented by Mr. H. J. Savage).

Kuitpo Industrial Colony (Rev. S. Forsyth).

Young People's Employment Council (Mr. E. D. A. Bagot).

Chamber of Commerce (Mr. Norman H. Taylor).

Returned Sailors and Soldiers' Imperial League (Mr. H. Thomson, M.C., K.C.—afterwards replaced by Mr. R. Jacob).

Commercial Travellers' Association (Mr. R. B. Norton).

Local Government Association (Mr. J. S. McEwin).

Commonwealth Employment Council (Mr. W. Queale).

Adelaide Trades and Labour Council (Mr. A. G. Angel).

Port Adelaide Trades and Labour Council (Mr. J. C. Bietz).

Chairman of Unemployment Relief Council (Mr. B. H. Gillman).

Superintendent of the Labour Exchange (Mr. A. C. H. Richardson).

Lands and Survey Department (Mr. W. J. Colebatch—afterwards replaced by the Surveyor-General (Mr. J. H. McNamara)).

Chairman of the Finance Committee (Mr. R. R. Stuckey, C.M.G.).

Chairman of the Mining Committee (Dr. L. Keith Ward).

Chairman of the Publicity Committee (Mr. V. H. Ryan).

Chairman of the Land Settlement Committee (Mr. W. J. Spafford).

At a later date the Chamber of Building Manufacturers was represented by Mr. P. R. Claridge.

By Govt Photo lithographer

Mr. B. H. Gillman withdrew from the Council when he relinquished the position of Chairman of the Unemployment Relief Council, but as his successor, Mr. A. C. H. Richardson, was already on the Council it was unnecessary to replace Mr. Gillman.

Owing to the inability of the appointed Chairman (the Lord Mayor) to attend the meetings of the Council, it was necessary to place someone else in this position, and to the intense gratification of all members, the Government appointed Mr. Norman H. Taylor to be chairman of the Council.

The Secretary of the Employment Promotion Council is Mr. F. K. Dwyer (who is also Secretary of the Unemployment Relief Council), with an Assistant Secretary in the person of Mr. B. Pollard.

FINANCE COMMITTEE.

The Committee which deals with all financial matters for the Council consisted of:—Chairman (Mr. R. R. Stuckey, C.M.G., Under Treasurer), Messrs. R. B. Norton, W. Queale, Norman H. Taylor, and H. Thomson, K.C.

MINING COMMITTEE.

To investigate all requests for help in mining ventures, and to make recommendations on these matters to the Council, the Mining Committee was formed, consisting of:—Chairman (Dr. L. Keith Ward, Director of Mines and Government Geologist), Rev. B. E. C. Tuck, Messrs. E. D. A. Bagot, J. C. Bietz, and W. Queale, with whom were co-opted Messrs. Walkley (Sharebroker) and Gartrell (Instructor in Mining at the School of Mines).

PUBLICITY COMMITTEE.

At first it was considered important to have a strong Publicity Committee, as a lot of work would have been required to launch successfully and maintain a public appeal, but with the altered conditions, which meant working on financial grants, there was no need for extensive propaganda and publicity. The Committee consisted of:—Chairman (Mr. V. H. Ryan, Director of Immigration and Tourist Bureau), Lord Mayor, Canon Bleby, Messrs. E. D. A. Bagot and H. J. Savage.

LAND SETTLEMENT COMMITTEE.

Originally two Committees were formed, one the Land Settlement Committee and the other known as the Land Selection Committee, but it was soon found that there was no work for both groups, and so they were amalgamated shortly after the Council began to function. This made the Land Settlement Committee a rather large one, but so far it has not proved unwieldy, and its personnel consisted of:—Chairman (Mr. W. J. Spafford, Deputy Director of Agriculture), Rev. S. Forsyth, Rev. Wm. Hawke, Messrs. A. G. Angell, J. C. Bietz, B. H. Gillman, J. S. McEwin, J. H. McNamara, A. C. H. Richardson, and Norman H. Taylor, with whom were co-opted Messrs. H. J. Bishop and J. J. Macgowan of the Unemployment Relief Council.

WORK OF THE LAND SETTLEMENT COMMITTEE.

Where the settlement on land of men without financial resources of any kind is concerned, the sum of £40,000 is very small indeed, and because of this limitation of money, and remembering that little success has been secured anywhere in the World when it has been necessary to give 100 per cent. financial aid to settlers, the Land Settlement Committee was hard pressed to decide on a scheme which would get many people on land with a reasonable chance of earning enough to enable them to live without further Government aid, and to permit of them getting off the rations in a short space of time. After full consideration being given to all forms of primary production possible in our climate, and remembering that

Photo 1/6 34

Fowl houses and poultry yards after being in use for a few months Chon moeller growing right up to the poultry yards

By Govt Photolithographer

it would prove uneconomic to start men producing articles with which markets were already over-supplied, it was decided to concentrate on small holdings for mixed farming where poultry keeping would be the principal activity. At the time Great Britain was importing annually 259,252,010 dozens of eggs in the shell, and about 86,688,000 dozens as pulp, and of this total of 345,940,010 dozens, only 62,278,130 dozens were received from Empire countries, and the Commonwealth's share was but 9,182,060 dozens in the shell, and about 1,200,000 dozens as pulp.

It was believed that this type of settlement could be brought about at a lower cost per settler than any other, payable returns could be secured quickly, and provided the poultry activities were directed towards the production of eggs for export, no local industries would be interfered with, and further that there appeared to be every chance of the British Markets admitting our eggs without hindrance.

LAND FOR SETTLEMENT.

Because greenfeed constitutes such an important part of the food of poultry, indeed a plentiful supply appears essential to success, it was necessary to select land in localities where green fodders can be grown with certainty, and so all of the land-settlement activities of the Employment Promotion Council have been confined to the heavy-rainfall portions of the Adelaide Hills.

The Land Settlement Committee appointed a sub-committee to select land and decide on its subdivision into holdings, and this sub-committee has kept in mind at all times that each block must be capable of being made self-supporting as far as a water supply is concerned, it must possess sufficient land suitable for gardening purposes so that summer fodders such as Chou Moellier, Silver Beet, Mangels, Millet, &c., can be grown in large quantities as well as all of the vegetables and most fruits required by an ordinary household, and it must be large enough to support wholly at least two head of large stock. Preference to be given to scrub land, because of the lower value at allotment time, and because the presence of trees for posts for boundaries, fields, and poultry yards keeps down the money advances for equipment.

PROVISION OF LAND.

At the commencement of the Land Settlement Scheme, a careful combing of all districts with sufficiently good climate for the kind of settlement desired was made in search of Crown Lands that might become available, and although there was not a great deal to be found suitable country for subdivision into 33 blocks was acquired. When this land had been allotted it became necessary to purchase land, which added to the cost of settlement, but has proved satisfactory otherwise.

SELECTING THE SETTLERS.

As in the case of the choice of land, a sub-committee was appointed to select settlers, and in doing so has followed the direction given by the Council, and besides choosing men likely to make a success of their holdings has endeavoured to place large families so that a lot of children are removed from the city to be reared in the country.

No difficulty has been experienced in the number of men available, for even though the Council has never advertised the fact that land settlement was taking place and settlers were wanted, over 1,600 applications have been received for land from married men who claim to have had agricultural experience.

All applicants are required to fill in a questionnaire, and when land is available the sub-committee for the selection of settlers goes through the application forms and interviews about three times as many men as are required—first collectively, when an explanation is given of what help is forthcoming, and then individually to allow the members of the Committee to form an opinion of the experience and

By Govt. Photo-lithographer.
View of the principal buildings supplied, showing dwelling, shed, and fowl houses.

Photo 1/6/34.

capability of the applicants. At the interview each applicant is required to supply the names of two or three prominent persons to whom reference can be made as to the character of the applicant and what his behaviour has been during the past couple of years or so. The most promising of those interviewed are listed, the persons referred to are approached, and if the reports are favourable, a woman inspector is sent to the homes of the applicants and reports her opinion on the cleanliness, tidiness, and suitability of the wife of the applicant. This latter is a recent innovation which past happenings decided the Committee to adopt.

STARTING A SETTLEMENT.

Although it is the fixed policy of the Employment Promotion Council to encourage every man to work out his own salvation and to have no community ownership or community work after the blocks have been allotted, in the original opening up of a settlement there is need of community work such as clearing sites for buildings, making roads passable, bridging creeks, cutting fencing posts and fowl-yard poles, &c. For the purpose, the Council has loaned tents and camping equipment, and the men have lived on the settlement as single men until dwellings have been erected and all community work completed.

BALLOT FOR BLOCKS.

As soon as dwellings are available and community work finished, a ballot for blocks is taken in the presence of an officer of the Council, and after settlers have been given the opportunity to interchange blocks, a statement is signed by each of them affirming agreement with the ballot and satisfaction with the block received.

TERMS OF ALLOTMENT.

Land is allotted on Perpetual Lease under Section 33 of the Crown Lands Acts, the rent being fixed at $2\frac{1}{4}$ per cent. of the land value, with reductions during the first three years, so that the first year's rent is one-fifth of the amount which would be paid annually; the second year's rent is one-third of the said amount, and the third year's rent is two-thirds of the said amount.

BUILDINGS ERECTED.

The simplest of dwelling quarters have been provided, consisting of three-roomed habitations of wood and galvanized iron, with lean-to verandah, with the rooms unlined except for the ceilings, but with boarded floors and fireplace and cooking stove forming parts of the home. Close to the cottage is a galvanized iron shed and 2,000gall. tank, and somewhat removed, a closet.

For the proper management of the fowls, four poultry houses, capable of carrying 600 laying hens, have been erected to the specifications of the Government Poultry Expert (Mr. C. F. Anderson).

All other buildings, including cellar to hold eggs, cow shed, pig sties, and other sheds are provided by the settlers from materials on the holdings.

EQUIPMENT SUPPLIED AND WORK DONE.

The Employment Promotion Council has made provision to plough thoroughly 1 acre of gardening land, after it has been properly cleared, so that summer-growing green fodders and vegetables can be grown, and arranges to have 2 acres seeded down with Subterranean Clover and Superphosphate to provide greenfeed for a cow.

Ordinary gardening, fencing, and scrub-clearing tools are advanced, as well as greenfeed cutters, egg scales, and other poultry-handling appliances.

Seeds of vegetables and green fodders, and a few fruit trees are supplied to make certain that the homes are provided with vegetables and fruits, and that the greenfeed required by the livestock is produced on the holdings.

Photo 1/6 34
A plentiful supply of green forage is being grown for the birds on land which was under forest less than 12 months ago.

Ry Govt Photographer

Sufficient materials to fence the blocks, and prov to paddocks for big stock as well as some netting to protect the gardens from rabbits are forwarded to each man.

Foodstuffs for the poultry are provided from the Council's funds for at least six months after the pullets are supplied.

Where settlers prefer sinking for water sufficient rope is provided to assist in the work, otherwise contracts are let to sink earth dams to hold water.

LIVESTOCK PROVIDED.

The aim of the Council has been to supply each settler with 30 to 40 laying hens as soon as his poultry-houses and yards are ready to receive them, so that his family will have a supply of eggs for home use.

During the first Spring after occupation an effort is made to secure 400 White Leghorn pullets, eight weeks old, from the July-September hatching, and to add another 200 to the flock during the second year.

When sufficient greenfeed is available to do away with the need of providing foodstuffs, a cow is supplied, and when the cow is in occupation, a weaner pig is advanced every three months for one year, making four in all.

REPAYMENTS OF ADVANCES.

The Council has not yet decided what shall be the terms of repayment for advances made, but the present intention is to make them attractive enough to give settlers a chance of "Getting on their feet" before full interest and instalments are demanded.

REVENUE FOR THE SALE OF EGGS.

Until final arrangements have been made for the repayment of advances, settlers are receiving all monies paid for eggs, but the allocation of egg money must of necessity form a part of any financial arrangement decided upon.

SETTLEMENTS OCCUPIED.

In the search for Crown Lands suitable for the purposes of the Employment Promotion Council, a small block was found by the Land Selection Committee at Echunga, another at Bridgewater, and a very small Reserve near Jupiter Creek. Fortunately at about this time a fairly extensive block on the southern side of Willunga Hill was surrendered to the Crown which proved to be adaptable for really small holdings.

No more Crown Lands could be secured to help the Council place unemployed persons, and it then became necessary to purchase land that could be subdivided into small blocks. A small section adjoining the Echunga settlement was secured, and a good block of land at Meadows was purchased soon after.

SETTLERS PLACED ON HOLDINGS.

The land procured and subdivided by the Council is all within the heavy-rainfall zone of the Adelaide Hills, and has been subdivided to carry only as many families as have a good chance of making a success of their holdings.

At Echunga there are twelve settlers, nine of whom formed the first settlement of the Council, and three others were placed later, after purchasing a block of land adjoining the original settlement.

The small block near Jupiter Creek is occupied by one family.

At Bridgewater the block was large enough to carry four settlers.

The area on the south-east side of Willunga Hill was sufficiently extensive to be subdivided into nineteen sections, with every chance of the settlers doing well. As this group was rather isolated from the township, it was necessary to provide a school, and the name chosen for this poultry settlement was "Yundi"—an aboriginal word meaning "Feathers."

After many inspections of properties in suitable districts, an area of good quality land was purchased on the south-western corner of the township of Meadows which has been surveyed into 24 attractive blocks, admirably suited to the requirements of the Council.

REARING CHILDREN IN THE COUNTRY.

Keeping in mind the intention of the Council to try and place men likely to make a success of their holdings, and at the same time to get as many children as possible out into the country where they will be reared in health-promoting surroundings, no man has been selected who has less than four children in the family unless he has special qualifications. This policy has meant that a large number of persons have been transplanted to the country, and the occupied settlements contain:—

Bridgewater	4 families	27 persons	19 children
Echunga (including 1 at Jupiter Creek)	13 families	91 persons	65 children
Yundi	19 families	142 persons	104 children
Meadows	24 families	182 persons	134 children
Total	60 families	442 persons	322 children

EXPENDITURE ON EACH SETTLER.

Although there will be slight differences for individual settlers the Council has made all its calculations on an expenditure of £400 per settler, exclusive of the purchase of land, and if nothing extraordinary happens, it appears that this sum will be sufficient to enable settlers to make a success of their holdings.

Below is set out the actual expenditure on a settler at the first settlement started, *i.e.*, Echunga, and an estimate of what is still required to put him on his feet, and in ordinary circumstances no further expenditure should be necessary for any man, still the Council proposes keeping a reserve fund in case of any unforeseen happening:—

SUPERVISION.

When the Employment Promotion Council was formed the Hon. Minister of Employment and Industry arranged that any Government Officer who could be spared was to be available to help the Council in its work, and for the supervision of the settlement. The following Officers were chosen:—Mr. S. G. Brealey (Inspector of Buildings in Police Settlement Department), who attends to all matters connected with buildings and community work; Mr. C. F. Anderson (Government Poultry Expert), who attends to the purchase of pullets and fowls, and sees that matters are proceeding in the care and management of poultry; Mr. R. Hill (Agricultural Inspector), who attends the agricultural operations of the settlement.

Without these supervisors the scheme could not function, and much of the success attained so far has been due to their enthusiasm in trying to help and encourage these unfortunate to become farmers.

Photo. 1/6/34.
Extensive improvements, as well as land clearing, have been carried out by some settlers. The cellar and woodwork structures are well built.

By Govt. Photographer

PROGRESS MADE.

Considering that the settlers being helped by the Employment Promotion Council have been in occupation of their blocks of land for such a short time the amount of work done and the general progress made is really remarkable. The first settlement to be occupied was that at Echunga, where the men went into residence in the second week in June, 1933; the Bridgewater men were transported to their homes in the first week of July of that year; whilst those at Yundi were not placed until towards the end of September, 1933. The three settlers located at Echunga No. 2 Settlement were placed in possession of their blocks in the middle of February, 1934, whilst the 24 at Meadows had their furniture shifted and their families transported to their new homes towards the end of May, 1934.

The Council made all provision to supply those settlers in residence before the end of October, 1933, with at least 30 laying hens and 400 spring-hatched pullets of an age of 8 weeks, and although poultry raisers accepted orders fully sufficient for the purposes of the Council, some of them failed so dismally that the season closed with the Echunga and Bridgewater settlers receiving 30 hens and 300 pullets, whilst those at Yundi only obtained 40 hens and 240 pullets. This shortage of pullets has naturally affected the returns received by the settlers, and must delay the day when they will get off the rations. Every effort has been made to make good the shortage from the coming spring hatching as well as to provide a further lot of pullets for each settler.

All of the earlier settlers grew some summer fodders for greenfeed for the poultry, such as Chou Moellier, Silver Beet, Mangels, Millet, and Sudan Grass, the more successful ones producing all that was required by the birds. Early in the autumn plots of Barley, Rye, and Mustard were seeded, and the growth, which is really good in most cases, is being cut for the poultry at the present time.

On all holdings, two acres of land have been cultivated and sown with Subterranean Clover and Yorkshire Fog Grass, at the same time giving a dressing of superphosphate.

Almost without exception, settlers have produced quite a lot of vegetables, some men proving themselves to be such expert gardeners that they had a surplus to give to their neighbours. Those who were in residence soon enough were supplied with a few fruit trees, some of which have done really well.

Settlers at Echunga and Bridgewater have been sending eggs to market for some time, and although dwellings were not erected at Yundi until late September of last year eggs are now being marketed from this settlement as well. Cheques received for eggs have already aggregated £200, and although the rations of settlers have not been reduced by this sum, a considerable reduction has been made.

The Council only provides a simple dwelling of three rooms, but in practically every case settlers have soon made additions to these buildings, and quite a number of them have been converted into comfortable cottages.

EFFECT ON SETTLERS.

Considering that most of the settlers have been out of work for years, or at all events have only had casual employment, it is to be expected that the allotment of a block of land, giving as it does a fresh chance in life, would have a marked effect upon them. This has certainly proved to be so, and almost without exception the men have gone into camp with the enthusiasm of schoolboys, and by the time the ballot has been taken for the blocks of land, have recovered their self-respect and gained physical fitness, so that their general appearance is quite other than when they were first interviewed by the Selection Committee.

By Goot Photo lithographer.

Glimpse of clearings through the forest trees still left standing

Photo 1/6/34

The long period of unemployment appears to have so affected practically everyone selected that their main desire is to work, and the energy displayed in clearing land, attention to crops, and care of livestock has been really remarkable,

Although the wives of settlers were not known to members of the Council before taking up residence on the settlements, the effect of this transference to a block of land they can call their own has been obvious to all visitors who have interviewed them, for they clearly show that hope has returned to them, and in practically every case they are contented to remain in the country and work hard to help their husbands make a success of their holdings.

Equally important from all points of view, and probably more so from that of the value to the State, is the fact that the large numbers of children put in these settlements are being maintained in happy and healthy conditions, seeing their parents working hard, and when old enough taking part in most of the manual operations.

POSSIBILITIES OF SUCCESS.

Land Settlement schemes involving 100 per cent. financial aid have not been very successful anywhere in the world, and it is extremely difficult to hazard a guess as to what proportion of settlers will come out on top, although now that the original settlements have been in existence for more than a year, the position looks much more hopeful than it did at the commencement. If the price of export eggs is maintained at about the figure which has ruled during the past season, and if nothing is done to interfere seriously with the acceptance of Australian eggs on the British market, it appears probable that the proportionate success will be greater than the 40 per cent. thought likely when the scheme was inaugurated. Even if a high proportion of the settlers fail to make good as farmers, the successful settlement of some of them, the rehabilitation of the men to a frame of mind and physical fitness to appreciate work, the return of hope and contentment to the womenfolk, and the fact that so many children have been reared in healthy surroundings in the country, will make the trial well worth while.

TETANUS.

The Secretary of the Laura Bay Branch of the Agricultural Bureau reports the following symptoms of a sick horse:—"Nostrils distended, ears pricked, neck stretched out and stiff, eyes rolling and turned back when the head is moved suddenly."

Replying to this question, Mr. Alan H. Robin, B.V.Sc. (Government Veterinary Officer) says there appears to be no doubt that the case is one of tetanus. The following suggestions are given for the general treatment of animals affected with this disease:—"The patient should be placed if possible in slings in a darkened and isolated loosebox, the floor of which is soft, and a purgative dose of medicine given at the outset. Quietness of surroundings on the part of the person attending to the animal is essential, and if necessary to further deaden extraneous sounds, the animal's ears can be lightly plugged with cotton wool. So long as the animal can move its jaws freely, solid food may be given, but if the jaws become locked, then all food must be in the form of slops. Every three or four hours a lump the size of a pigeon's egg of green extract of Belladonna should be placed between the animal's teeth so that it can gradually swallow it down.

Further, if the means are available, 1½ozs. (3 tablespoonsful) of a saturated solution of Epsom salts can be injected intramuscularly or subcutaneously, half on each side of the neck, twice daily for 10 days, and then if necessary once daily for a further 10 days. These injections help to control the muscular spasms of this disease.

A very careful search should be made for any wounds through which the infection may have got in, and if such are found, all scabs are to be removed, the wounds if necessary further opened up, scraped with a knife or curette, and then packed with cotton wool plugs soaked in strong antiseptic solution or in tincture iodine, these

SOME NOTES IN GENERAL ON THE CONSTRUCTION OF BUILDINGS.

[By T. A. MACADAM, Dip. Arch. (Glas.), A.R.A.I.A., Lecturer in Architecture and Building, School of Mines, Adelaide.]

The question may be asked: What does a farmer want to know about building construction, and why should he be specially interested in it? The answer to both questions is that, as a rule, the farmer usually is the owner of the property and desires to know how to keep it in order. He is different from the average man in business, who usually rents the premises where he conducts his business and has, therefore, no interest in the property. Another reason for a farmer's special interest is the fact that farm buildings are usually situated many miles from a centre where building material and skilled labour are available. There is also the position of the farmer who is purchasing a farm, unless he knows something about the construction of buildings he may lose on the deal. A farmer beginning a new farm will save time, labour, and expense, as well as know how to make use of the materials he may find on the site if he has a knowledge of the construction of buildings. Then again there is a period of the year when the farmer is not working full

time, and he may not be able to keep all his labour employed. This period gives him an opportunity to repair his buildings, alter them, or make additions, if necessary.

In building construction, labour, generally speaking, is a large factor in the cost. If the farmer has the labour he only requires the knowledge of construction to use that labour to the best advantage and in this way keeps the cost down.

Taking a general survey of building construction first, the more important points, such as a good foundation, ventilation, prevention of damp, &c., may be referred to, and the simplest procedure will be to take a building, such as a house, for the base of our subject.

FOUNDATIONS.

Beginning with the foundation, unless a building has a good foundation it will be a source of trouble and expense later. To be sure of a good foundation, whether it be of concrete, stone, or a stump foundation, the first point to notice is, that the ground which supports the foundation is properly drained. (See sketch A.) No water should be allowed to collect near the foundations. Next see that the soil is strong enough to support the foundation. The heavier the building the stronger the soil must be. Foundations should be level. A sloping foundation will tend to move with any vibration.

In modern building construction cement concrete is largely used for foundation. Lime concrete is used where limestone can be obtained locally. Stumps or short posts are also used, chiefly for wood or iron buildings.

Whatever materials you use see that they are fresh, clean, and, if possible, new. Do not use old cement, old lime, or faulty timber if the best results are desired.

As cement concrete is used so much for foundations as well as for other parts of buildings, a few details concerning it will not be amiss. The mixing of the materials must be done carefully if the maximum strength is to be obtained. This requires some knowledge of the materials which are being mixed. For example, the sand may be fine or coarse and the gravel may be large or small, and these would affect the mixture and the strength. (See the article on "Concrete on the Farm," by W. Trestrail, in the *Journal* for August, 1933. Also "Cement Concrete Posts for Fencing," by W. J. Spafford, published in Bulletin No. 225.)

Several points are essential in the mixing, one being the proportioning of the parts of gravel, sand, cement, or lime, another the thoroughness of the mixing of the materials, and mixing with the minimum of water. Mix the materials on a clean, hard surface and use a measure, such as a kerosene tin or wooden box, to get the proper quantities of each material. Do not mix any more than you are going to use at the time. After depositing the concrete in its position see that it is made as solid as possible by spading it or use a trowel to get an even surface. The next step is to see that the concrete is kept wet or damp for some time after it is in position, as this will tend to increase the strength of the concrete. The warmer the weather the longer the concrete should be protected. The increase in strength in the concrete will more than repay the time and labour involved in protecting it. While on the subject of cement concrete, a reference should be made to reinforced concrete. Most concrete foundations are reinforced with steel rods for the reason that the strength of the concrete is greatly increased when steel rods are used to reinforce it. Place the rods lin. from the bottom of the foundation and in

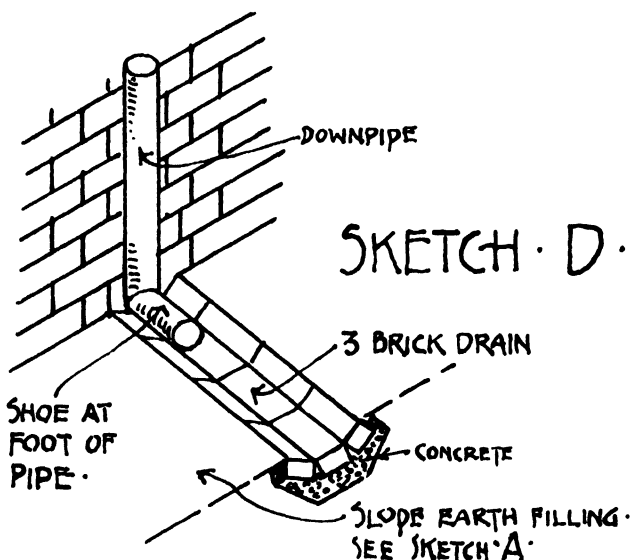

a similar position at the top of the foundation if necessary. Keep the rods straight in their length, and hook them together at junctions. (See Sketch A.) Overlap them at corners.

WALLS.

Having placed the foundations in position, the next step is to build the walls. These must be strong enough to support the roof, &c., and keep out the weather. They may be built of stone, brick, concrete, or wood and iron. Whatever the material, precautions should be taken to prevent damp from reaching the inside of the wall. Damp may rise from the ground to the inside of the wall, and to prevent this in the case of masonry walls a damp proof course of tar and sand, lin. thick, is spread over the full thickness of the wall above the outer ground level. In very wet districts two layers 12in. apart, may be used. Damp may also penetrate through the wall from the outside. To overcome this, the simplest and best way is to build a cavity wall. (See sketch A.) With brick walls it is simple, but where stone is in use it is a different proposition owing to the stones being of various sizes and shapes. If bricks were obtainable it would be better to build the outer portion in 4½in. brick and have a 2in. cavity between it and the 12in. or 14in. stone wall inside. Where stone has to be used special care must be taken when building the walls so that the joints between the stones will not become channels for the water to find its way to the inside. Stone, like brick, is porous and will be a conductor of moisture, so that every precaution has to be taken to

keep the damp out. The undersides or beds of the stones should be built level and the joints properly filled with good mortar. Lime mortar is composed of three parts of clean sharp sand and one part of run lime, well slaked. See that they are thoroughly well mixed.

The walls may be built of concrete, either by placing the concrete in position direct or by making concrete blocks and building them in position later. Considering the block method first, the blocks are made by mixing one part of cement with seven of sand, and damping only sufficiently to enable the mixture to hold together when pressed into the hand (like flour). Place the mixture in the mould and ram tightly and evenly. When block is removed from the mould keep it covered with damp bags for a week. The size of the blocks would be approximately 9in. x 6in. x 6in. The principal advantage blocks have is that they can be made in spare time and stacked for use. With a solid concrete wall certain precautions should be taken. If the walls to be built are walls exposed to wet weather a mixture must be used which will make a weatherproof concrete. This means a richer mixture than would be necessary for walls which are protected by verandahs or by walls of other buildings adjoining them. It would be advisable to use one part of cement, two of sand, and three of gravel. Place the concrete in the wall in layers 9in. to 12in.

in depth and ram it well. At door and window openings see that the wooden frames do not project beyond the line of the concrete or the boards will require to be cut at each frame. When the walls are being built, whether in brick or concrete, the frames for the windows and doors are usually built into them. They are fixed to the wall by galvanized iron straps which are built in. On the tops of all frames flat galvanized iron should be fixed to protect them from damp which may affect the wood.

ROOFING.

The walls being erected, the next step is the roofing. This is usually a simple matter, but care should be taken to see that the roof is well secured to the top of the walls where it rests. It is not sufficient to rest the roof on the walls, it should be bolted down or strapped down. In addition to being a fixing for the roof it also assists in tying the walls. Another point to observe is the roof should be braced. Bracing is necessary if the roof is to stand any exceptional wind pressure.

Various materials are used for roof coverings, such as slates, tiles, &c., but none is so good and cheap as corrugated galvanized iron. Like all other materials, it has

fixing. In very exposed situations or where the wind can get in below the iron, such as an open verandah roof, special precautions should be taken. The ordinary galvanized nail is not sufficient to keep the iron down on such roofs. Galvanized roofing screws should be used, and every other flute secured. When nailing or screwing down iron see that the head of the nail is not driven below the top of the flute, as depressed flutes allow the rain in. It will pay to use a good washer with the roofing nails or screws. When walking on a galvanized iron roof see that you walk on the part which is nailed, as the iron is supported there, and there is not the same likelihood of the flutes being dented. If a roof has to be walked on frequently, then boards should be placed on the roof for the purpose. If this is not done the nail holes gradually get widened until they are not weatherproof. When fixing the gutters in position see that they have a fall towards the rainwater tank or downpipe. If there is not sufficient fall in a gutter then there is a tendency for water to lie in the gutter until it dries out, and while drying out it is likely to rust the gutter. It will pay to examine the gutters before each winter and have them thoroughly cleaned out. In addition to preventing debris and leaves, &c., from entering the rainwater tank or downpipe, it also prevents, to a certain extent, the rusting of the tank, if it is an iron one. When placing the downpipes in position, see that they are placed so that the water from them will run away from the building and not lie near the base of it. A good plan is to put a shoe on the end of the pipe, and below the shoe put a length of concrete or brick drain, about 8ft., which will convey the water some distance from the house before it begins to soak into the soil.

VENTILATION.

While on the subject of roofs, the question of roof ventilation might be referred to. This is a matter which is very frequently neglected. Between the ceiling and the underside of the iron roof the air space enclosed should be ventilated as much as any room of a house. This can be done in several ways, and it does not matter much which way is adopted, provided it makes for good ventilation. Someone may say: Why is it necessary to ventilate the roof space? Well, if that person will go into a roof which is not ventilated on a hot day, and then go into one which is properly ventilated, the reason will be obvious. Apart from the necessity for ventilating the roof timber, it makes for a cooler building. Inlet and outlet ventilation must be provided if it is going to be effective. Various forms of ventilators are on the market for the purpose. The same attention should be given to the ventilation of the air space below the wooden floor (See sketch A.) Before a floor is laid the space which is going to be covered should be cleared of all debris, especially scraps of timber. Any timber left under a floor will only encourage white ants and other insects. Openings should be placed in all outside and inside walls below the floor to ensure a thorough current of air, the more openings the better will be the ventilation. The reasons for ventilating the space under the floor are as follows:—(1) To ventilate the timber under the floor. (2) To prevent dry rot and white ants. (3) To keep the space dry and free from damp or wet rot. (4) To keep the building cooler in hot weather and generally make it healthier to live in.

(To be continued.)

CATALOGUE OF SCIENTIFIC PERIODICALS.

The Library of the Department of Agriculture acknowledges the receipt of Supplement (1928-1933) to the "Catalogue of Scientific and Technical Periodicals in the Libraries of Australia" published by the Council for Scientific and Industrial Research. Copies are available at a cost of 5s. per copy, plus 4d. postage. Copies of the original catalogue, together with the supplement, may be had for 12s. 6d., plus 1s. postage. Orders should be placed with the Tait Publishing Co., 39, Queen Street, Melbourne.

THE WANDERING GRASSHOPPER.

[A report by Mr. H. D. Adams (Agricultural Instructor) on the appearance of grasshoppers on Eyre's Peninsula has been submitted to Dr. J. Davidson, D.Sc., of the Waite Agricultural Research Institute, whose remarks on the life history of the insects and on suggested control measures are given below.]

The grasshopper which has been recently present in large numbers over certain areas of southern South Australia is a small brownish species with silvery wings. It is known as the Wandering Grasshopper (*Chortoicetes terminifera*), and occurs over wide areas in Australia, more particularly in the drier regions.

The female lays its eggs in areas of bare soil; the eggs are contained in an egg-sac which is buried in the soil by the female, with the aid of its ovipositor.

The insects occur throughout the summer months, and the eggs which are laid in the autumn take a long time to develop, owing to the low temperatures; they usually hatch from September to November, according to district and the weather during the winter months. From these eggs the young wingless "hoppers" emerge. They feed on the vegetation and eventually become winged. When winged they make somewhat indefinite migrations in swarms. The swarms may be patchy and not evenly distributed over an area. This appears to be due to the adults of a swarm laying their eggs in a restricted area. There is very little definite detailed information regarding the habits of this species in Australia. There appear to be two or three broods during the summer. These broods overlap, and this would be the explanation of a report that the young grasshoppers were hatching out in the Minnipa district.

The grasshoppers in general keep to cleared, open type of country. They do not normally extend so far south in South Australia as occurred this autumn. The present occurrence may be due to the prolonged dry weather.

If the swarms extend late into the autumn, the insects may damage young wheat crops and lucerne. The conditions which influence the survival of the eggs in the soil during the winter are not known; it is possible that the wet, cold conditions in the southern portion of this State are unfavourable for the survival of many eggs. If this is so, the hoppers may not be so numerous, when the over-wintering eggs are due to hatch in the spring. The number of grasshoppers present this autumn suggests they may occur in numbers if the eggs can withstand the winter conditions.

The numbers of the grasshoppers vary in different years; this appears to be due to weather conditions, but definite information with regard to this species is small.

The best control is obtained by destroying the "hoppers" soon after emergence from the eggs. Spreading arsenic bait in the line of their advance is the usual method. The poison bait can also be used against the winged forms, but it is more effective against the hoppers.

Observations should be made from about the end of August, to see whether hoppers are hatching out; these situations should be defined so that bait treatment may be used where desirable. Co-operation amongst the settlers in this respect would be helpful.

Some observations on this species of grasshopper and control measures were given in the *Agricultural Gazette* of New South Wales, and the following poison bait was recommended:—

Arsenite of soda, 1lb., or paris green, 3lb. to 1lb.

Molasses, 4lbs.

Bran, 24lbs.

Water, 3galls.

The arsenite of soda is dissolved in hot water. After cooling, the molasses are added and stirred until dissolved. This liquid is added to the bran and mixed to form a crumbly mash. If paris green is used the powder should be added to the dry bran; water is then added to make a crumbly mash. The bait is spread at the rate of 20lbs.

THE IMPORTANT PASTURE PLANTS OF SOUTH AUSTRALIA, CONSIDERED AS TO THEIR INDENTIFICATION AND CHARACTERISTICS.

[By E. M. HUTTON, B.Ag.Sc., Field Officer.]

INTRODUCTION.

In general a pasture consists of a mixture of grasses, clovers, and other plants which are often termed weeds. In this paper it is intended to review pasture plants found in natural pastures as well as those which are now sown in pastures to improve their productivity. For the purpose of the paper, pasture plants will be considered in three sections, viz., the grasses, the clovers, and plants other than grasses and clovers.

A. THE GRASSES.

All grasses belong to the large grass family or *Gramineae*. Grasses are made up of fibrous roots, stem, leaves, and seed head. For the purpose of identification, leaves are important during the non-flowering or vegetative period, while the seed heads are important when the grass is approaching maturity. The roots are important in the identification of the Canary grasses.

Fig. 1.—Showing parts of a Grass.

The leaves have a lower portion, the leaf sheath which sheaths or surrounds the stem, and an upper free portion, the leaf blade (see Fig. 1).

Running the length of the leaf blade is a number of parallel veins, the central one being thicker and known as the midrib. At the junction of the leaf sheath and leaf blade are found the ligule, and in some cases the auricles (see Fig. 1). The ligule is a small whitish or colourless flap which presses against the stem. Often the ligule is very minute and in some cases is represented by a semicircle of hairs. The auricles are a pair of small clasping processes which hold on to the stem.

The presence or absence of hairs on the leaves or near the ligule, and the character of the emerging leaf shoot, *i.e.*, whether spirally rolled or flattened are important points in identification. There are two main kinds of seed heads:—An open branched one or panicle, and an undivided one or spike. The parts of the seed head which bear the seeds are called spikelets (see Figs. 2 and 3).

The grass family can be divided up into a number of groups or genera, the grasses within each group resembling one another.

I.—THE RYE GRASS GROUP OR *LOLIUMS*.

These are hairless grasses with a pair of auricles. Leaves have a characteristic bright green colour. The lower surface of the leaf blade is smooth and shiny, while the upper surface is ribbed. The leaf sheaths at the base of the plant are purplish.

The seed head of the Rye grasses is in the form of a characteristic spike (see Fig. 2), each spikelet being placed edgewise to the stalk. True Perennial Rye Grass has a very slender seed head, while Drake or Darnel has a coarse seed head, each spikelet being very much swollen when mature.

Fig. 2.—Showing Spike of a Rye Grass.

Fig. 3.—Showing Open Panicle of Weeping Love Grass.

1. TRUE PERENNIAL RYE GRASS (*Lolium perenne*).

In an established pasture Perennial Rye Grass can be recognised by its perennial tufted habit. Young plants can be recognised by the general rye grass characters, and by the fact that the emerging leaf shoot is sharply flattened (see Fig. 4). This distinguishes it from Wimmera Rye Grass in which the emerging leaf shoot is definitely rolled.

True Perennial Rye Grass is very resistant to grazing and is ideal for milk and butter production. It needs heavy soils high in nitrogen, *e.g.*, heavy dark loams and clays. In addition it needs the more temperate conditions and 20-25in. rain is probably about the minimum for persistence and productivity. Perennial Rye Grass is very persistent around gates, stables, and under trees where it withstands the trampling of stock, and benefits from the dung and urine. It shows all the advantages of a perennial, *e.g.*, rapid production feed with first autumn rain. In the year of planting it is very vigorous and has a strong

depressing effect on slower establishing grasses like *Phalaris tuberosa*. Once established it is necessary to keep up the nitrogen supply of the soil by stimulating clovers with a topdressing of superphosphate. With a heavy rainfall it may be of advantage to apply dressings of sulphate of ammonia.

2. WIMMERA RYE GRASS (*Lolium subulatum*).

The identification of this grass has already been mentioned. As its name implies, it originated in the Wimmera district of Victoria, and it is believed to be a cross between Perennial Rye Grass and Italian Rye Grass.

Wimmera Rye Grass will grow successfully in the cereal cultivation belt, and it should become important where the rainfall is less than 20in., e.g., Lower and Upper North. It forms an ideal temporary pasture for farmers—if about $\frac{1}{2}$ h. per acre of Wimmera Rye Grass is sown with the wheat in autumn at harvest time the seed formed will be scattered by the harvester. This seed will then produce an excellent temporary pasture for sheep the next year.

Wimmera Rye Grass possesses the main disadvantages of all annuals, i.e., before a bulk of feed is produced the seed must germinate and the plant must be given time to develop. It produces seed rapidly on the advent of dry conditions, and thus it should be spelled in late spring to allow of seed setting.

Fig. 4.—The Emerging Leaf Shoots. In (1) True Perennial Rye Grass, (2) Wimmera and Annual Rye Grasses. In each case a shoot cut across is shown.

Like Perennial Rye Grass it has a high nitrogen requirement. Thus it thrives well on a fallow, and after Subterranean Clover or Pease. Tilth and a good nitrogen level in the soil appear necessary for Wimmera Rye Grass. In the absence of cultivation, and Subterranean Clover or nitrogenous manures, it will tend to disappear gradually. Cultivation is necessary to cover the seed for germination. Thus it appears necessary to cultivate Wimmera Rye Grass pastures every two or three years, and grow Subterranean Clover in conjunction with it.

3. ITALIAN RYE GRASS (*Lolium Italicum*).

This is not important here, because it flowers very late with the result that the delicate flower structures are dried up by the summer heat and no seed is formed. It has a rolled leaf shoot and has strongly awned spikelets.

4. RIGID RYE GRASS (*Lolium rigidum*).

This is a common weed which is the shortest of all the rye grasses. It has characteristically curved leaves. It produces very little seed, and has a low food

5. DRAKE OR DARNEL (*Lolium temulentum*).

This is a tall growing weed, which is often poisonous to stock because of the presence of a fungus. It can be recognised by the mature spikelets being greatly swollen.

II.—THE CANARY GRASS GROUP OR PHALARIS GRASSES.

Like the *Loliums*, these are hairless. They possess no auricles and the emerging leaf shoot is rolled as in the annual rye grasses. They have a very large ligule, and if the young shoots are cut near the base, the sap will be found to be purple.

The *Phalaris* grasses have a characteristic seed head, the flower scales of which are oval and marked with white and yellowish-green stripes (see Fig. 5).

1. TOOWOOMBA CANARY GRASS (*Phalaris tuberosa*, ALSO KNOWN AS *Phalaris bulbosa*, *Phalaris stenoptera*, AND *Phalaris stenophylla*).

With young plants having the general characters of the *Phalaris* group, *Phalaris tuberosa* is indicated if the young root tips are almost colourless and the stem base is pink. In the case of the non-persisting annual *Phalaris minor* or wild Canary grass, the young root tips are a bright pink. If one is doubtful of the seed bought, a germination test by placing seeds on moist blotting paper in a warm place should be carried out: Colourless root tips show *Phalaris tuberosa*, yellow root tips show *Phalaris canariensis*, bright pink root tips show *Phalaris minor*.

When the young *Phalaris tuberosa* plants stool, the additional stems arise below the soil and then grow through the soil at an angle before reaching the surface, and this makes it very resistant to grazing. Established plants show up as

Fig. 5.—Showing seed head of *Phalaris tuberosa*, which is 6-8 times as long as broad.

vigorous perennial tufts which tend to increase in circumference. The leaves are broad, light green, and succulent.

Phalaris tuberosa is especially prized, because it produces greenfeed with the first autumn rains, and is able to resist the hot dry summer because of its underground swollen stems and long roots, which penetrate deeply into the moist subsoil and keep the plant alive.

It has been grown successfully in rainfalls varying from 17-36in., and is admirably suited for grazing cattle. It appears to do better on the heavier soils, but should persist on light soils with a heavy subsoil.

In the first year, *Phalaris tuberosa* does not tiller very actively, during which time it must be carefully handled to prevent eating out of this relatively slow establishing grass. In the second autumn the grass is highly vigorous and becomes firmly established. It might be interesting to note here that recently I observed some *Phalaris tuberosa* plants which have persisted through the severe summer droughts of the last few years on Mr. H. K. Moore's property at Jamestown.

2. THE WILD CANARY GRASSES (*Phalaris minor* AND *Phalaris canariensis*).

These grasses grow under the same conditions as are favourable to wheat. *Phalaris minor* is the common one found, while *Phalaris canariensis* is never found wild and is cultivated for canary seed.

They are easily distinguished from *Phalaris tuberosa* by their annual habit, and the colour of their young root tips.

Although they are excellent fodder plants producing soft succulent feed, they disappear under grazing and have the disadvantages inherent in all annual grasses.

(To be continued.)

PASSION FRUIT GROWING.

[By GEO. QUINN, Chief Horticultural Instructor,]

The principal points in securing good results in the cultivation of this plant may be summed up as follows:—

It is desirable to have a good, rich, free-working, well-drained soil located in a place not subject to very heavy frost during the winter months, as these plants are very readily injured by severe frosts.

The kind of Passion Fruit usually grown is the ordinary *Passiflora edulis*, which comes practically true from seeds.

The general method of raising passion vines is to take the seeds out of good types of fruits and sow them straight away—before they have had time to dry out—in boxes or sheltered beds made up of good, free, sandy soil which can be kept well watered. The seeds are covered to a depth of about $\frac{1}{2}$ in. with loose soil made up of sand and rotted manure, which is pressed fairly firmly on to the seeds. The fruits selected about June may be kept until August in a cool place, when the seeds are extracted and sown.

The seedlings, when sufficiently advanced—that is, when they are 4 in. or 5 in. high, should be transplanted either into boxes or pots in the first case, placing them about 4 in. apart, so that they may be lifted with a ball of earth when ready to go out into the orchard. The young plants should be trained to a single stem. They are planted in the field in rows very much like grape vines are, the rows being 9 ft. or 10 ft. apart to allow for implements to cultivate the soil, and the plants are set out from each other in the rows about 6 ft. to 8 ft. They are trained somewhat fan-shaped on a trellis resembling a 5-wired fence, but above the height of an ordinary agricultural fence. Plants may be bought from nurserymen at about 6d. each, and set out of the pots without receiving any check.

The best time to set out these plants is in the early spring when most of the frosts are over, but they should be watered in when planting, and kept watered about once a fortnight for the first three months—if it is only a matter of giving them a bucketful of water. The tillage necessary approximates to that usually given grape vines; whilst the pruning consists of cutting out exhausted shoots as they accumulate, thus keeping up a supply of laterals on which the fruits are carried.

As to the profitable character of growing them, that would depend very much on the time when the fruit becomes available for marketing, but they have the advantage over most fruits, that they are not readily injured by ordinary transport procedures. It never appears to be very cheap, and no particular effort has been made to push the sale of it or to induce greater quantities being used. It is doubtful if it would be a wise procedure for anyone to take up the growing of passion fruit only, on a large scale, until, at any rate, one becomes accustomed to the requirements of the market and the methods of handling the crop and the plants.

BORERS IN STONE FRUIT TREES.

[By GEO. QUINN, Chief Horticultural Instructor.]

The principal borer attacking stone fruit tree stems and limbs is the larva or caterpillar of a moth figured in French's "Destructive Insects of Victoria," Part I., page 112, under the name *Maroga gigantella*. (It is more often now called *Cryptophasa unipunctata*.) The moth has a wing spread of about 2½ in., the front wings being creamy white in colour with a single dark dot—hence the name "unipunctata"—in the middle of each wing. The hind wings are of a plain gray colour. The fully grown caterpillar found in the tunnelled wood is about 1½ in. long by nearly a quarter of an inch thick. The head is black and the next two or three

segments dark-brown; the rest of the body of a pale creamy-yellow colour. It is a native insect, and the larvae are often found in Banksia or native honeysuckle trees.

The moths deposit their eggs in crotches or forks where limbs join the trunk or on the trunk itself, and particularly like places where gum may have exuded owing to some damage or twist. When the small caterpillars hatch, they gradually tunnel under the bark and raise masses of sawdust-looking frass. They continue boring in these softer parts until fairly well grown, and then they strike into the hard wood of the limb or stem. There is not, to my knowledge, any effective way of preventing the moths depositing on the trees—though winter oil sprayings may do so—but the young caterpillars soon reveal their presence by the evidence of the newly pushed out sawdustlike borings. If when the stone fruit trees—including almonds—are bare of leaves, it needs no very close scrutiny to detect these evidences of boring having commenced.

At this early stage a strong knife or scraping tool will quickly remove the shallowly located borers, and a coating of Stockholm tar or old paint will cover the wound from the wet or drying air. At these early stages only very minute semi-transparent grey-looking little caterpillars are found. If not dealt with in the early stages, the caterpillars—as previously remarked—tunnel into the wood and may take either an upward or downward or devious course.

The best procedure when borer hunting is to scrape away sawdust, gum, &c., until the mouth of the tunnel is revealed. Push a flexible wire in as a probe and note whether the end is wet or slimy when withdrawn—indicating the pest is well punctured. If the tunnel is very irregularly bored, the wire will probably fail to prick the culprit. It then becomes necessary to suffocate the borer, and the best reagent is Carbon Bisulphide put on to a little cotton waste or wadding, and thrust into the tunnel, which is immediately plugged airtight with clay or a close-fitting wooden plug. I am told that the fumes of ordinary petrol evaporating from cotton

or wool waste used in a similar manner will also kill the borers, but have not tested it. The fumes of burning sulphur would be effective if they could be injected into the tunnel before closing it against their escape.

These pests are not difficult to control, but careful attention during each winter is desirable where the pest has been found much in evidence. The South Australian raised varieties of almonds are most prone to "gunming" and this encourages the egg-laying upon such sorts.

ENSILAGE COMPETITION—HILLS DISTRICT.

The following are the results of the Ensilage Competition conducted by the S.A. Committee of Australian Dairy Council and judged by Mr. R. Hill (Agricultural Instructor):—

Competitor.	Address.	Position.	Suitability of Plants. 15	Success- lency. 20	Palata- bility. 15	Nutritive Value. 35	Percent- age of Waste. 15	Total. 100

In a detailed report on the entries Mr. Hill stated that the winning stack, exhibited by Mr. A. E. Francis, of Bugle Ranges, was 12ft. x 12ft. at the base, reduced to 9ft. square at the top. The crop was cut very early, as soon as the Silver grass commenced to show heads, and the stack was covered with earth 1ft. in depth. The mixture consisted of Subterranean clover, a big percentage of Silver grass, some soft Brome grass, sterile Brome grass, wild oats, and some Perennial Rye grass. The result was excellent ensilage with very little wastage. The labour used to cut and weight the stack (which contained approximately 25 tons) and 47 hours for a man and a youth, using a sweep and grab; and a further four hours were occupied in erecting the grab and in other preparations.

TURRETFIELD SEED WHEAT.

HARVEST REPORT—SEASON 1933-34.

[By R. C. SCOTT, R.D.A., Supervisor of Experimental Work, and F. E. WADDY, Farm Manager.]

The Turretfield Farm lies in the hundred of Barossa and adjoins the township of Rosedale. In situation it is placed about 35 miles north of Adelaide or 10 miles in a north-easterly direction from Gawler. The total area is 1,604 acres, but that available for cropping is considerably less since the North Para River and Salt Creek run through the property, taking up approximately 100 acres of land. In addition, about 250 acres comprises rough, hilly country which is only suited to grazing, whilst when that occupied by plantations, buildings, &c., is taken into consideration only about 1,250 acres are available for the planting of crops.

On the whole the soil is of a red loam type with some patches of calcareous land, whilst the flats adjoining the river are more or less silty in nature. A serious

Turretfield Seed Wheat Farm Homestead.

disadvantage so far as the soils of Turretfield are concerned is the prevalence of red clay patches which tend to run together and set hard after rain.

From the years 1920 to 1932 the farm was conducted on a commercial basis, and all farming costs recorded.

However, at the conclusion of that period the Government of the day approved of the proposal that the work should be confined to the production of pure seed wheat for disposal to farmers. As this decision was not arrived at until late in the season only preparatory work could be carried out in that year. However, during the past 12 months a definite system of plant selection has been commenced which, when the full rotation has been completed, will render available supplies of pure strains of seed wheat.

THE SEASON.

The weather conditions experienced during the past year have been most unusual. Not only was the rainfall irregularly distributed, but the extremes of temperature, particularly those recorded in late Spring and early Summer, were such as to affect seriously the setting and proper maturing of the wheat grain.

Particulars of the rainfall at Turretfield are shown in the following table:—

Rainfall at Turretfield.

	1932.	1933.	Means, 1908-1933.
	Ins.	Ins.	Ins.
January	0.45	1.44	0.56
February	0.99	0.13	0.73
March	0.92	0.57	0.76
April	2.60	0.92	0.82

"Useful" Rainfall.

	1932.	1933.	Means, 1908-1933.
	Ins.	Ins.	Ins.
Seeding rains (April-May)	3.74	3.96	3.22
Winter rains (June-July)	6.27	2.14	4.25
Spring rains (August-October)	6.44	6.68	6.12
Early Summer rains (November)	0.34	0.36	0.96
Total	16.79	13.14	14.55

The mean fall over the past 26 years is 17.56in., of which 14.55in. has fallen during the growing period of the wheat crops.

For 1933, 16.33 in. were recorded, of which 13.44in. may be regarded as "Useful." Consequently the registration was approximately 1½in. below the mean, but the chief feature of the season so far as rainfall is concerned was the manner in which this amount was distributed.

Good rains fell in May (304 points), but the month of June and the early part of July were unusually dry and cold.

For August and September 267 points and 329 points were registered respectively, with the result that all crops made vigorous, healthy growth. However, in October and November the falls were scanty, thus limiting the development of plants, but the most serious feature was the extremes of temperatures recorded in the former month.

On October 19th and 22nd hot winds raged, and on the latter date a shade temperature of 98° F. was reached, whilst four days later a particularly severe frost was experienced, which cut the vines in the district and blighted the ears of wheat crops which were in a certain stage of development. Until these conditions were experienced the harvest prospects were exceedingly bright, and whilst many crops made a good recovery after the cooler weather experienced in the following weeks, it is estimated that the ultimate wheat yield is 8bush. to 9bush. per acre less than that which would have been gathered if normal ripening weather had occurred.

HAY HARVEST.

The great bulk of the hay area comprised headlands and the divisions cut between varieties. In all, 190 tons were stacked, including 34 tons secured from stubble land planted with oats for grazing purposes.

The individual yields obtained are tabulated below:—

Field.	Variety.	Acreage.	Total Yield.		Acre Yield.		
			T.	C.	T.	C.	L.
No. 7—Sword	16.3	51	0	3	2	65
No. 3—Sword and Caliph	15.5	45	0	2	18	72
No. 15—Nabawa	5.82	13	10	2	6	44
No. 6—Sultan	6.36	14	10	2	5	67
No. 3A—Waratah	4.08	8	10	2	1	75
No. 1—Ranee	2.93	5	10	1	17	61
No. 5—Federation and Gallipoli	12.1	18	0	1	9	84
		63.09	156	0	2	12	70

In addition to the above figures 34 tons of oaten hay were cut from 42.12 acres of stubble land in Field No. 9, which was planted for the purpose of providing grazing for livestock. After having been regularly fed off until late in the season it was eventually allowed to develop for hay, and ultimately returned 16cwts. 16lbs. of good quality material per acre. However, as this was essentially a chance crop it is not included in the mean hay yield for the farm. The average yield of 2 tons 12cwts. 70lbs. is very satisfactory, particularly when it is remembered that the great bulk of this was cut from the headlands and divisions which rarely yield as well as the main crop.

The best return tabulated is that from 16.3 acres of Sword in Field No. 7, namely, 3 tons 2cwts. 65lbs. per acre. This comprised the whole of the field and the crop, which originated from purchased seed, was cut for hay because it was not sufficiently true to type for our purposes.

However, probably an even higher yield was secured from 6 acres of Sword planted on a rich flat in No. 3, which had not been cropped for a number of years. This was not weighed separately, but as the crop was dense and almost 6ft. in height it must have yielded at least 3½ tons of hay per acre.

Sword can therefore be recommended as a wheat capable of producing heavy yields of good quality hay, but at the same time no comparison with the other varieties named in the table is possible since none of these were cut from regular blocks.

WHEAT HARVEST.

The whole of the wheat crops were seeded in good time on well-prepared fallow ground, and planted at the rate of 75lbs. of grain together with 150lbs. of super-phosphate per acre.

In all, 348 acres were devoted to wheat, and the yields obtained are shown in the following table:—

Field.	Variety.	Acreage.	Total Yield.		Acre Yield.	
			Bush.	Lbs.	Bush.	Lbs.
No. 3—Sword	29.85	966	32	32	23
No. 3—Sword	4.22	120	6	28	28
No. 3—Caliph	20.23	536	24	26	31
No. 6—Sultan	30.30	759	48	25	5
No. 15—Nabawa	69.61	1,527	36	21	57
No. 1—Ranee	24.24	522	10	21	2
No. 5—Gallipoli	57.14	892	16	15	37
No. 3A—Waratah	32.50	425	30	13	6
No. 5—Federation	51.25	527	38	10	18
No. 3—Selection Plots	28.70	889	3	—	—
		348.04	7,167	3	20	36

No comparisons between the yields from the different varieties are possible since the fields were planted at varying times whilst the soil conditions are not similar throughout all paddocks.

However, in this connection comparisons can be drawn when the averages from the seed plots are being considered.

The mean yield from 348 acres is 20bush. 36lbs., which is quite satisfactory, but not as high as originally anticipated.

The frost severely affected some varieties, and it is estimated that the loss from this cause approximated 5bush. per acre in the case of Sword, 6bush. with Caliph, 8bush. with Ranee, Gallipoli, and Sultan; 10bush. with Nabawa, and 15bush. with Waratah.

The best yield was harvested from an area of almost 30 acres of Sword planted in Field No. 3. This amounted to 32bush. 23lbs. per acre, and was followed by a return of 28bush. 28lbs. from another block of the same variety.

The poorest averages were secured from Gallipoli, Waratah, and Federation. That from Waratah was due almost entirely to the action of frost since the growth made was very satisfactory, whilst those from Gallipoli and Federation were brought about by eel-worm attack in patches of Field No. 5.

Seed Plots, 1933-34.

Variety.	Acreage.	Total Yield.		Acre Yield.	
		Bush.	Lbs.	Bush.	Lbs.
Waratah	2.26	79	5	35	0
Ford	2.06	70	15	34	6
Sword	4.17	139	30	33	27
Gallipoli	4.22	130	23	30	54
Ghurka	2.78	85	43	30	50
Ranee 4H	4.83	142	27	29	30
Nabawa	2.42	69	22	28	44
Sultan	1.04	29	53	28	44
Federation	4.92	140	25	28	32

The nine wheats listed above constitute the varieties which will be handled at Turretfield with the object of creating a limited supply of pedigreed seed wheat. In the course of time some will no doubt be replaced with more suitable types that happen to be evolved. However, it is not proposed to include any number of varieties in this work, but to concentrate on about eight or nine of the most important.

The system adopted for the selection and building up of supplies which will be available for sale to farmers consists of four stages, namely:—

1. *Stud Plots*: In which the grain from hand-selected ears is planted in spaced rows. From these plants the most valuable strains will be isolated and typical ears from the best plants gathered for the continuation of the stud plot in the following year.

2. *Selection Plots*: In which the grain harvested from the stud plots after the stud ears have been picked will be seeded.

3. *Seed Plots*: In which the grain harvested from the Selection Plots is seeded.

4. *Commercial Seed Plots*: In which the grain harvested from the Seed Plots will be planted and will supply the seed wheat to be offered for sale.

From the foregoing it will be noted that four years must elapse before the plan of selection will be in full operation and, therefore, as the work has only been in progress for two seasons the wheats quoted in the previous table have not been built up from stud ears but were developed from plants seeded in spaced rows in 1933, and then carefully worked over to remove any impurities or undesirable types. Examination of the table shows that Waratah, Ford, and Sword have given the maximum yields, whilst Nabawa, Sultan, and Federation are practically equal for bottom position.

In this connection it might be added that all of these plots were seeded side by side, and consequently so far as this season is concerned the yields obtained are comparative one with the other.

In all cases the grain harvested was of good quality and the crops free from disease, although different varieties were more or less injured by frost.

Only two wheats, namely, Ghurka and Ranee 4H, are not well known to farmers.

Ghurka was bred by the Victorian Department of Agriculture, being a cross between Indian H x Federation and Currawa. It is a hardy, short strawed, heavy yielding variety which should suit the red lands of South Australia.

Ranee 4H is a selection from Ranee (Indian F x Federation) made by the Victorian Department in which the other types present in the original Ranee have been eliminated and an improvement effected.

AGRICULTURAL EXPERIMENTS IN SOUTH AUSTRALIA.

[By R. C. SCOTT, R.D.A., Supervisor of Experimental Work.]

EXPERIMENTS IN THE SOUTH-EASTERN DISTRICTS.

Under the arrangement in which private farmers work in co-operation with the Department, agricultural experiments are progress at Keith, Kongorong, and Millicent.

In addition, wheat variety tests were commenced at Wolseley, but as the experimenter was unable to continue the work over the full period, there are no results of value to report upon.

The character of the experiments include wheat and pasture variety trials on different types of land at Keith, manurial tests with sown and natural pastures at Kongorong, and trials with imported wheat varieties at Millicent.

Harvesting Wheat Experimental Plots at Keith.

EXPERIMENTS AT KEITH.

The Keith district is situated about 150 miles from Adelaide and is served by the Adelaide-Melbourne railway. It lies on the fringe of what is usually described as the Ninety-Mile Desert country, and the land varies considerably in quality. That in the vicinity of the township is quite good agricultural country, capable of yielding heavy cereal crops and producing a luxuriant growth of pasture, whilst on the outer or plain country the soil is sandy and, generally speaking, of low fertility.

* The former area consists chiefly of sandy loam soil overlying a limestone rubble and limestone rock subsoil, whilst in those patches where the sand tends to predominate the land is liable to drift.

In the latter area the sand is coarser in texture and varies in depth from a few inches to over 2ft. It rests on a layer of tough clay which in its turn overlies fairly solid limestone rock.

In both of these types of soils agricultural experiments are in progress.

Winter (June-July)	5.32	4.50	3.80	5.68	6.83	1.75	4.65	4.47
Spring (August-October) .	5.63	4.69	7.50	4.97	5.43	5.60	5.65	5.80
Early Summer (November)	0.39	1.09	1.26	0.43	0.63	1.74	0.92	1.12
Total	14.98	13.25	15.37	14.25	15.73	14.78	14.74	14.80

The average annual rainfall at Keith is almost 18ins., whilst the "Useful" fall totals 14.80ins. Therefore, so far as the rainfall alone is concerned, and not taking the nature of the soil into consideration, the district is well treated for the growing of annual crops. However, examination of the tables will show that only a little more than 3ins. is recorded during the four months extending from December to March inclusive. Consequently, the less hardy perennial pastures have difficulty in carrying through the summer, whilst in an average season the seed-producing capacity of late-ripening annual plants is affected.

During the past six years the average falls have approached the means of the 1907-33 period, but in each season special conditions have been recorded. In 1929, 1931, 1932, and 1933 late Spring and early Summer rains were scanty, with the result that normal maturity of the crops was affected, whilst in addition, conditions favourable to the development of Red Rust were experienced in 1932.

Other extremes recorded were dry cold months in August 1928, June 1930, and June 1933, during which all plants received a severe set-back.

EXPERIMENTS ON THE PROPERTY OF MR. W. E. GILL.

Wheat variety experiments have been conducted on the property of Mr. Gill, which is situated in the better class land of the Keith district. The results secured are shown in the following table:—

Wheat Varieties, Keith.

Variety.	1928.	1929.	1930.	1931.	1932.	1933.	Means.	
							1930-33.	1928-32.
	B. L.	B. L.	B. L.	B. L.	B. L.	B. L.	B. L.	B. L.
Bena	30 20	29 13	9 2	19 33	15 26	—	—	20 43
Sultan	24 31	26 36	8 58	22 22	11 43	—	—	18 52
Dan	20 19	27 27	8 43	14 38	12 42	—	—	16 46
Federation .	17 53	28 44	7 56	19 2	9 27	26 1	15 37	16 37
Major	21 1	26 9	8 14	17 24	9 11	—	—	16 24
Gallipoli ...	—	—	13 11	24 22	13 1	27 4	19 25	—
Ford	—	—	—	—	—	22 13	—	—
Sword	—	—	—	—	—	21 58	—	—
Waratah ..	—	—	—	—	—	20 54	—	—
Nabawa ..	—	—	—	—	—	20 23	—	—

Reviewing the yields from the varieties seeded over the five-year period 1928-1932 it will be noted that *Bena* has given the highest average, with a mean return of 20bush. 43lbs. per acre. *Sultan* occupies second position with 18bush. 52lbs., whilst there is very little difference between the remaining three, each being about 2bush. less than *Sultan*. *Gallipoli* has been included in the experiment since 1930, and during the four seasons has headed the averages on three occasions, whilst the mean yield from this variety over the full period is 19bush. 25lbs.

On account of the damage caused by Red Rust in the 1932 crops it was decided to introduce a number of new wheats, and the yields secured from these varieties are set out above.

Viewing the results as a whole it would appear that *Gallipoli*, *Bena*, and *Sultan* are the most suitable varieties for planting on the better class land in the Keith district.

However, provided that the varieties are planted on good fallow land, rather higher average yields than those tabulated can be anticipated, since in two years out of the six, namely 1930 and 1932, Take-all and Red Rust respectively played havoc with the crops.

EXPERIMENTS ON THE PROPERTY OF MR. L. H. DENSLEY.

Pasture experiments have been conducted by Mr. Densley on land of much the same quality as that on which the Wheat varieties have been planted. The class of experiment consisted simply of Pasture variety trials, each plot being about one-tenth of an acre in area and the whole collection set out in the same field so that all fodders received similar conditions of grazing. The full area was manured annually at the rate of 1½cwts. of Superphosphate per acre. The varieties seeded and remarks concerning the growth made are as follows:—

Perennial Rye Grass:

This Grass made good growth in the early years after planting, but later on died out rapidly. The plot was seeded with ordinary commercial Rye grass, as at that time certified seed was not obtainable. Experience has since shown that the latter is much superior regarding length of life and other desirable qualities, and there is little doubt that had certified seed been available this would have developed into a very satisfactory pasture.

Wimmera Rye Grass:

This has proved the best of the grasses. Each season it has made a good body of feed, but in recent years the foliage has exhibited a light green colour and made rather less growth than anticipated. This is probably due to lack of association with a clover which would assist in supplying the nitrogen requirements.

Cocksfoot:

A number of plants of cocksfoot have persisted notwithstanding the dry summer conditions, but on the whole, this grass does not appear to be of much value for the district.

Phalaris tuberosa:

The seed purchased in 1929 as *Phalaris tuberosa* proved to be *Phalaris minor*. A good crop of the latter resulted, but being an annual which does not possess persistent seeding habits, it died out in the course of two years.

The plot was then cultivated and seeded with *Phalaris tuberosa*, but experience with this fodder has indicated that good tillage is essential for a satisfactory stand, and consequently only a few plants managed to survive the competition with weeds.

As a result, no information regarding the value of *Phalaris tuberosa* is available.

Chewing's Fescue:

The seed germinated well, but the plants did not make headway and practically disappeared after the first summer.

Kentucky Blue:

The development of this variety was very similar to that of Chewing's Fescue, and in the third season it had died out completely.

Sheep's Burnet:

The plants persisted well and individually made fair growth, but the body of feed was never great.

Creeping Bent:

Has yielded a limited amount of short grazing, but does not appear to have much value for these conditions.

Chicory:

This variety has shown considerable promise, persisting throughout the dry summers, and yielding an appreciable amount of palatable fodder.

Evening Primrose:

One of the strongest growing plants seeded in the experiment. Because of its deep rooting habits it was able to firmly establish itself in the deep sands. At the same time it has provided good pasturage and proved one of the best varieties for the lighter soil conditions.

Lupins:

In the first year a poor germination of lupins was obtained, but the plants steadily thickened up until in the last season the crop was both tall and dense. However, under the Keith climatic conditions the grain does not appear to be readily palatable to livestock, whilst the plants themselves are not eaten at all. This is the reason why the stand has improved in recent years.

From the point of view of improving soil fertility or checking the drifting of sandy land, the planting of lupins may be recommended, but in this area they do not appear to have much value as a fodder crop for livestock.

Danthonia pilosa (Wallaby grass):

This grass has taken a long time to develop, and although producing little feed in earlier years, has steadily improved and now provides useful grazing.

Ehrharta longiflora (Annual Veldt grass):

Seed of this grass was gathered from plants growing on sandy land near the sea coast, west of Adelaide. Attention was drawn to the variety, which is an annual, because of the strong growth made early in the season and its free seeding habits.

At Keith it has successfully re-seeded itself each year and gives promise of becoming a useful pasture plant for the poorer land.

King Island Melilot:

On the sandy type soil the Melilot has not persisted and the plants died out rapidly.

Bokhara Melilot:

This variety has made fair development and at times has yielded good grazing, but latterly the plants have thinned out.

Lucerne:

Has proved far and away the best fodder in these plots. In the years in which satisfactory summer rains were experienced a crop sufficiently well grown to allow for mowing was obtained, whilst throughout the full period very good grazing has been secured.

Black Medic:

This pasture has not proved of value and at the end of the second season had almost disappeared.

White Clover:

The growth made by White Clover was poor and the plants failed to carry through the summer.

Strawberry Clover:

The soil and climatic conditions were not suitable for this clover and consequently the young plants did not persist.

Clustered Clover:

Appears naturally in the district and consequently the addition of seed, together with regular and adequate dressings of superphosphate, resulted in the development of a thick and strong-growing stand. Clustered Clover was easily the best of the clovers.

Subterranean Clover:

The Subterranean Clover seeded in this plot was of the Mount Barker strain. As the annual rainfall is less than 18ins., it was not surprising to find that except under unusually favourable late spring and early summer conditions, this type was unable to set its grain satisfactorily, and consequently could not provide sufficient seed for the following year.

As a result this strain is not suitable, and the earlier maturing type, grain of which is now obtainable, should be much more valuable in this area.

From the foregoing, it can be concluded that lucerne is the best fodder for planting under conditions similar to those in which the experiments were conducted, whilst other fairly satisfactory pastures are Wimmera Rye Grass, Clustered Clover, and Evening Primrose. In addition it would appear that if the best strain of Perennial Rye Grass and Subterranean Clover was secured, both of these fodders could be included amongst the valuable varieties.

EXPERIMENTS CONDUCTED ON THE PROPERTY OF MESSRS.
T. A. & A. S. DICKSON.

The land on which experiments are being conducted by Messrs. Dickson is quite different to that on which the other experimenters at Keith are working.

It has recently been reclaimed from its virgin state, under which it carried yacca, together with occasional patches of stunted mallee. The soil is a low fertility sand, but overlies a yellowish clay of fair quality.

The experiments comprise tests to determine whether cereals can be planted as a first crop and also pasture variety trials to indicate those most suitable for such land.

CEREAL EXPERIMENTS.

In the first two seasons oats were planted on land which had been ploughed for the first time in the previous August and on which the yaccas remaining after ploughing had been hand grubbed.

The oat varieties included Algerian, Lachlan, Kherson, Early Burt, Fulghum, Palestine, and Imbros Island. They were seeded early in the season, together with 180lbs. of Superphosphate per acre, with the object of providing sheep grazing and subsequent harvesting if the later development would permit.

The grazing secured amounted to half a sheep per acre per annum, but the grain crop was almost a total failure. The varieties Kherson, Early Burt, and Palestine gave the best yields of fodder, but failed to make further headway, whilst on the other hand Algerian and Imbros Island gave practically no grazing, but produced a small quantity of grain. These results were not satisfactory, and accordingly wheat varieties were substituted in seasons 1931 and 1932. Owing to the dry conditions experienced in October in the former year, only 33 points being recorded, the wheat crop failed altogether and no harvest figures were secured.

However, in the next season the following yields were obtained:—

Nabawa	12bush. 18lbs. per acre.
Ford	10bush. 9lbs. per acre.
Gluyas	8bush. 48lbs. per acre.
Felix	5bush. 38lbs. per acre.
Faun	4bush. 54lbs. per acre.
Federation	3bush. 51lbs. per acre.

From the experience gained during these seasons it would appear that cereal-growing on such land is attended with considerable risk, and unless intended as a preparation for pasture crops is not to be recommended. However, if wheat is to be planted the varieties Nabawa and Ford have proved the most satisfactory.

PASTURE EXPERIMENTS.

There is little doubt that this land is unsuited to regular cereal cropping, but, on the other hand, there is every possibility that, assisted by the average rainfall recorded, it could be built up to fair grazing country.

With this object in view the land would first of all be ploughed to destroy the natural growth and possibly a cereal crop planted, so that further tillage could be given prior to sowing with pastures.

In an attempt to ascertain the most suitable fodders a collection of varieties was planted on land which had carried one cereal crop.

The results obtained over the past four seasons have been as follows:—

Perennial Rye Grass:

The plants made good growth at first, but in subsequent years died out rapidly, and at the end of the third year very few remained.

Wimmera Rye Grass:

This is one of the best plots. The plants have seeded freely and made strong growth, but regularly show evidence of Nitrogen deficiency. Last season a strip was dressed with Sulphate of Ammonia and a marked benefit was noted, particularly in the healthy appearance of the plants. Under ordinary pasture management this requirement could probably be made good by planting in conjunction with a Clover, when the legume would assist in supplying the nitrogen requirements of the grass.

Cocksfoot:

Failed to survive the conditions and at the present time has practically disappeared.

Phalaris tuberosa:

The plants have persisted fairly well and stooled out considerably. However, not very much feed has been produced, a fact which is probably due to the lack of fertility. At the same time it is the best of the perennial grasses, and as soil conditions improve so should *Phalaris tuberosa* become more valuable.

Danthonia pilosa:

The Wallaby grass in this plot only provides fair grazing. It was very short in the first season, but has improved with age.

Yorkshire Fog:

Not enough rain is received for Yorkshire Fog and most plants have succumbed.

Gheuing's Fescue:

A fair mat of this grass has persisted, although the growth is very short.

Waipu Brown Top:

This variety has done quite well and the ground is coated with fairly short grass. It appears to be much more palatable to stock than the other grasses of similar type included in the experiment.

Creeping Bent:

Has developed about equally with Brown Top, but is not eaten as readily by livestock.

Kentucky Blue:

Only a relatively thin stand of this grass has persisted.

Couch grass:

Germinated satisfactorily and has obtained a good hold. This plot has yielded a fair amount of short grazing, particularly in those seasons in which good summer rains have been recorded.

Chicory:

Has given one of the best pastures, both with regard to quantity and palatability of the fodder. All livestock appear to be particularly fond of it. At one time kangaroos entered the plots and dug for the roots, ultimately leaving the ground in a stirred condition as if pigs had been confined on the patch. Its deep taproot permits it to withstand severe weather conditions, and Chicory appears to be a very useful plant.

Evening Primrose:

The Primrose has made good development, and in the same way as the Chicory has penetrated to the clay, thus firmly establishing itself against summer drought. Good feed has been produced, and consequently Primrose can be regarded as one of the best varieties for these conditions.

Sheeps Burnet:

Individual plants have made good growth and persisted well, but viewed as a whole the plot has not yielded much feed.

Lupins:

The variety planted was New Zealand Narrow Leaf. As soil improvers they have done well, but do not appear to have appreciable value as a food for live stock. The plants have spread over the adjoining plots, and at times have made dense growth approximately 3ft. in height. So far as is known Lupins have not been utilised for ensilage in South Australia, but it is reported that in parts of Europe they are frequently availed of for this purpose and so converted into a palatable foodstuff. In view of the fact that Lupins are useful soil renovators and consequently of use for the lighter lands their value for silage purposes is worthy of investigation.

Bokhara Melilot:

This plant does not appear to be very long-lived, but at one period showed to advantage.

At the present time many plants have died out and the area is not as attractive as previously. However, it appears to be a useful variety and has yielded a satisfactory amount of grazing.

King Island Melilot:

The Melilotus was practically a failure, and despite a strong germination the plants did not thrive.

Lucerne:

In addition to the Lucerne planted in this plot Mr. Dickson has also seeded a small area on similar country. The results obtained are very encouraging, the plants having developed into strong, healthy crowns and yielding very useful grazing.

There is little doubt that ultimately Lucerne will be extensively sown in this class of country.

Clustered Clover:

The seed purchased under this name contained only a small percentage of Clustered Clover, and mainly comprised Drooping Clover. The former has done well, and is one of the best in the series, but the latter is not particularly valuable.

Subterranean Clover (Mount Barker strain):

The strain has persisted fairly well, although the thickness of the stand has varied from season to season according to the character of the preceding Spring weather. It has proved a very good fodder, but as adverse Spring conditions may lead to a poor setting of grain and consequently a thin crop in the following year, the earlier ripening strains are to be preferred.

Subterranean Clover (Early strain):

The seed used in this plot originated from an early ripening plant forwarded from Western Australia and built up in the pasture plots at the Adelaide Show Grounds. In maturity and characteristics it is very similar to that now on the market as the Dwalganup strain.

Its early maturing habits permit it to set grain by the middle of August, with the result that danger of poor seeding due to adverse Spring weather is practically avoided. In growth characteristics the Early strain is more "stemmy" and

smaller-leaved than the later maturing type, and therefore would never be preferred unless the climatic conditions rendered the seeding of this strain advisable.

In the plots at Keith it has always seeded freely and a good dense mat of fodder maintained.

Reviewing the Variety experiments, the best plots have been Wimmera Rye Grass, Waipu Brown Top, Chicory, Evening Primrose, Lupins (from growth point of view only), Bokhara Clover, Lucerne, Clustered Clover, and Early Strain Subterranean Clover.

The grasses generally made growth indicative of nitrogen starvation, and when a strip across all plots was dressed with Sulphate of Ammonia the response was very marked. However, it is doubtful whether such application would be economic comparatively with the planting of mixture containing both grasses and clovers.

These Variety plots served to indicate the grasses and clovers which were most valuable for the locality, and from the information thus gained two pasture mixtures were planned for seeding on two-acre plots in 1933.

The mixtures planted were:—

Plot 1:

5lbs. Wimmera Rye grass per acre.

5lbs. Early strain Subterranean Clover per acre.

Plot 2:

3lbs. Clustered Clover per acre.

3lbs. Bokhara Clover per acre.

2lbs. Evening Primrose per acre.

2lbs. Chicory per acre.

Both plots were seeded on land which had carried one cereal crop and were fertilised at the rate of 2cwts. of Superphosphate per acre. The germination was satisfactory, although the Subterranean Clover was not as thick as anticipated.

As these plots have only been established for one year, little comment is possible, but from the results obtained it would appear that the mixture planted in Plot 1 will prove very suitable and yield more grazing than that in Plot 2.

EXPERIMENTS AT MILLMOENT.

The work at this centre consists of tests with imported wheat varieties which were sown in comparison with those regularly planted in the wetter and more fertile soils of the South-East. In the past the efforts of Australian wheat breeders have been largely directed towards the production of types better suited to the drier areas.

In such areas the normal growing period is relatively short, and it follows that whilst the later ripening types which have been evolved in Australia are better suited to our cooler districts, there may be higher yielding varieties available from those countries in which cool wet-growing conditions are regularly experienced.

Consequently the Departments of Agriculture in Tasmania and New Zealand were asked to supply particulars relative to their more important varieties.

Tasmania reported that the most widely grown wheat was Braemar Velvet, constituting about 32 per cent. of the area planted, whilst about 24 per cent. was seeded with Federation.

In New Zealand the chief varieties were Solid Straw Tuscan, Hunters and Velvet Chaff, all of which had a growth period of almost eight months.

Accordingly, the above three, together with Braemar Velvet, were imported and tested on the properties of Messrs. Sapiatzer and Fenson Bros. in the years 1931 and 1932 respectively.

Unfortunately, the small amount of Braemar Velvet secured was so much reduced by attack from pests that it had to be sent to the Kybybolite Experimental Farm

for multiplication purposes, but the mean yields from the remainder, together with that from Major, are shown below:—

Variety.	Mean Yield 1931-32.	
	Bush.	Lbs.
Major	27	52
Hunters	16	39
Velvet Chaff	13	31
Solid Straw Tuscan	10	21

From the above figures it will be noted that Major gave very much higher returns than any of the imported wheats.

The difficulty with the latter was their liability to rust and the long period that elapsed between full bloom and maturity. Despite early planting, they failed to ripen their grain satisfactorily and did not show much promise in these tests.

EXPERIMENTS AT KONGORONG.

The experiments at Kongorong are connected with the manuring of sown and natural pastures. They were commenced in 1924 on the property of Messrs. Morrison Bros., but four years later this partnership was dissolved, and for the

Pasture Experiments at Kongorong: 2cwts. Superphosphate Plot, immediately before cutting for Meadow Hay.

past five seasons the experiments planned for Plots 1 to 4 have been conducted by Mr. W. Crowe, and those occurring on Plots 5 to 9 by Mr. E. E. Morrison.

The Kongorong district lies about 20 miles to the south-west of Mount Gambier and the land on which the plots are placed is typical of the locality.

The area surrounding Kongorong comprises rather bleak open country on which, prior to the adoption of top-dressing, feed made very slow growth during the winter months.

The soil is relatively shallow and is of light loam type, which in its turn overlies fairly solid limestone rock. The rainfall approaches that recorded at Mount Gambier, and in the table following the monthly precipitation, together with the means for Kongorong and Mount Gambier are set out.

December	0.38	1.61	2.30	0.36	2.01	1.25	0.19	1.58	0.78	1.15	1.63
Total...	26.43	25.77	23.14	24.70	25.86	23.33	22.05	32.72	22.38	25.11	30.55

The above rainfall returns indicate that since these plots were established drier years have been experienced than is usually the case in this district. For the nine seasons the annual fall has been 25.11 inches, whilst the mean for 72 years is 30.55 inches.

Pasture Experiment at Kongorong. No Manure Plot, not grazed.

The value of the rainfall is largely dependent upon its distribution, and in this locality it is a disadvantage to receive heavy downpours during the winter months, particularly if dry weather should be experienced in late Spring. What may be regarded as a relatively good season occurred in 1930, when mild winter conditions were followed by good rains extending into early summer. In this year feed was abundant and heavy grazing returns were secured from those plots receiving full manurial dressings.

PLAN OF EXPERIMENT.

The plan of experiment consists of 9 plots each 5 acres in area. Seven carry natural pasture and are top-dressed annually with various fertilisers, whilst two were sown with pasture grasses in 1924. In the latter the acre mixtures comprised:—

<i>Plot 1:</i>	10lbs. Wimmera Rye Grass.	<i>Plot 2:</i>	1lb. Sheeps Burnet.
	2lbs. Subterranean Clover.		2lbs. Wimmera Rye Grass.
<i>Plot 2:</i>	3lbs. White Clover.		2lbs. Creeping Bent.
	1lb. Alsike Clover.		2lbs. Cocksfoot.
	2lbs. Black Medic.		2lbs. Yorkshire Fog.

The grazing result from each plot was practically equal, but in later years many of the varieties planted in Plot 2 died out and were replaced with Subterranean Clover, seed of which had been carried in from adjoining fields by animals.

In this collection of fodders Subterranean Clover was the outstanding variety, none of the others approaching it in body of foodstuff produced. Wimmera Rye Grass has also done fairly well, but under these conditions and the use of certified seed Perennial Rye Grass would probably be more satisfactory.

The best of the remainder were White Clover, Alsike Clover, Sheeps Burnet, and Cocksfoot, and all of these are worthy of inclusion in any pasture mixture. Others which showed up fairly well but are not particularly useful fodder plants were Creeping Bent and Yorkshire Fog.

In 1931 various changes in the Manurial dressings were made and the grazing returns from each plot prior to these changes, namely, the period 1925-30, are shown in the next table:—

Pasture Plots, Kongorong, 1925-30.

Plot.	Pasture.	Manure per Acre.	Sheep per Acre per Annum.						
			1925	1926	1927	1928	1929	1930	Mean.
1. ...	Wimmera Rye Grass Subterranean Clover	1cwt. Raw Rock Phosphate	0.97	1.45	1.75	2.34	2.59	2.64	1.96
2. ...	Sown Fodders	1cwt. 45% Super	1.32	1.75	1.35	2.52	1.92	2.82	1.95
3. ...	Natural Pasture ...	1cwt. 45% Super	0.92	1.42	1.73	2.83	2.29	3.79	2.16
4. ...	Natural Pasture ...	1cwt. Raw Rock Phosphate	0.66	1.20	1.19	2.46	1.56	1.73	1.47
5. ...	Natural Pasture ...	1 ton Lime (1924) 1cwt. 45% Super (annually) 10cwt. Raw Rock Phosphate (1924)	1.61	1.58	1.93	1.93	2.33	2.51	1.98
6. ...	Natural Pasture ...	1cwt. 45% Super (1924)	1.33	1.58	1.60	1.99	1.81	1.40	1.62
7. ...	Natural Pasture ...	No Manure	0.54	0.39	0.41	0.61	0.88	0.35	0.53
8. ...	Natural Pasture ...	1cwt. 33% Bone Manure	0.64	1.02	1.30	1.65	1.88	1.15	1.27
9. ...	Natural Pasture ...	1cwt. Raw Rock Phosphate	0.74	0.97	1.74	1.69	1.49	1.18	1.30
		1cwt. Sulphate of Potash							

In these experiments ground raw rock phosphate (82 per cent. acid soluble phosphate) has been utilised on a number of plots with the object of determining its value for pasture top-dressing comparatively with superphosphate.

So far as the ground imported rock is concerned the price relatively to superphosphate is too great to warrant consideration, but there is a number of low-grade phosphatic deposits in South Australia which if finely ground and available at a sufficiently cheap rate would possibly be useful for top-dressing in the higher rainfall areas.

In the foregoing table the yields obtained from the varying manurial dressings have been shown on a sheep per acre basis notwithstanding the fact that at times different classes of livestock have been grazed upon the experimental area.

In comparing the sown pastures (Plots 1 and 2) it will be noted that the yield from each is practically equal, namely, 1.96 and 1.95 sheep per acre respectively. This result has been obtained despite the fact that the former plot has received an annual dressing of 1cwt. of raw rock phosphate and the latter a similar quantity of 45 grade superphosphate. However, in this case no conclusion regarding the value of these two fertilisers can be drawn, since the improved pasture following the Wimmera Rye Grass, Subterranean Clover seeding, comparatively with the other mixture planted, has served to counterbalance the benefit gained by the use of the more readily soluble phosphatic manure. Dealing with the advantage of sown fodders comparatively with natural pasture, attention is drawn to the fact that in Plot 4 the natural pasture topdressed with 1cwt. of rock phosphate per acre has yielded grazing for 1.47 sheep, whilst the sown pasture in Plot 1, which received a similar manurial dressing, has given a mean grazing for 1.96 sheep per acre per annum over the six-year period.

From these figures it can be concluded that in the Kongorong district the sowing of a pasture mixture will lead to an increased grazing capacity of at least half a sheep per acre per annum, with the probability that when superphosphate is utilised the advantage in favour of sown pasture comparatively with natural

pasture would be still further increased. Examining the yields from the natural pasture plots, the outstanding feature is the low grazing return secured from the area (Plot 7) which has not received any manurial dressing. The grazing in this case only amounts to 0.53 sheep per acre per annum, and even this figure is higher than would be the case if sheep were maintained continuously on an unmanured area, since with 5 acre plots the flock is simply turned in from time to time according to the pasturage offering. On the other hand, Plot 3, which receives 1cwt. of 45 grade Superphosphate per acre, has maintained 2.16 sheep per acre, or, in other words, has yielded four times as much grazing as the unmanured area. Consequently, it can be concluded that adequately top-dressed land in the Kongorong district will carry four times as many sheep or cattle as it could prior to top-dressing, and moreover would maintain such animals in better health.

In connection with annual applications of raw rock phosphate, a 1cwt. dressing (Plot 4) has produced sufficient pasture for 1.47 sheep—a reduction of 0.69 sheep per acre comparatively with that obtained from 1cwt. applications of 45 grade Superphosphate.

Assuming that the value of the grazing of one sheep equals 12s. 6d. per annum and the cost of superphosphate and raw rock phosphate is 5s. and 4s. per cwt. respectively, the additional outlay of 1s. per acre for superphosphate comparatively with that required for raw rock phosphate has lead to an increased return of 8s. 8d., or a net profit of 7s. 8d. per acre.

Therefore, it would appear that before raw rock phosphate can be suggested as an economic fertiliser for pastures it must be available at rates very much below those at which it is offered to-day.

Little can be said regarding the remaining manurial dressings, as the results do not show to advantage when compared with those obtained from annual dressings of superphosphate.

In these soils lime is apparently not required, whilst a heavy application of raw rock phosphate every 10 years is not as effective as lighter annual dressings. Further, the use of either bone manure or sulphate of potash has not proved economic under these conditions.

In 1931 an alteration in the manuring of Plots 5, 7, and 9 was effected, and the results since that year are set out below:—

Pasture Plots, Kongorong, 1931-32.

Plot.	Pasture.	Manure per Acre.	Sheep per Acre. per Annum.		
			1931.	1932	Means.
1	Sown fodder	1cwt. Raw Rock Phosphate .	2.11	1.88	2.00
2	Sown fodder	1cwt. 45% Super.....	2.68	1.44	2.06
3	Natural pasture ...	1cwt. 45% Super.....	2.72	2.40	2.56
4	Natural pasture ...	1cwt. Raw Rock Phosphate .	2.28	1.79	2.04
5	Natural pasture ...	2cwts. 45% Super	2.65	2.86	2.76
6	Natural pasture ...	10cwts. Raw Rock (1924) ..	1.54	2.14	1.84
		1cwt. 45% Super (1924)....			
7	Natural pasture ...	No manure	0.56	0.64	0.60
8	Natural pasture ...	1cwt. 45% Super.....	1.44	2.38	1.91
		½cwt. Sulphate Ammonia .			
9	Natural pasture ..	1cwt. Raw Rock Phosphate	1.51	2.50	2.02
		½cwt. Sulphate Ammonia ..			

The results are available for only two years, but the most important feature has been the improvement in the grazing capacity of Plot 5 since 2cwts. of Superphosphate per acre have been applied. This plot has given a mean grazing return of 2.76 sheep per acre over the two seasons and jumped to the head of the averages, whereas for the six-year period 1925-30, during which time it received 1cwt. of superphosphate annually, the yield was only 1.98 sheep per acre.

The addition of Sulphate of Ammonia to Plots 8 and 9 has also had considerable influence and much improved grazing has been secured from each.

In conclusion of this report dealing with the Kongorong plots it is desired to place on record our appreciation of the work of the experimenters, Messrs. Morrison and Crowe, in keeping careful records of the stock depastured on the plots and in the interest they have shown in the work being conducted.

STATE OF SOUTH AUSTRALIA.

FINAL RESULTS OF CEREAL AND HAY HARVEST, 1933-34.

[By W. L. JOHNSTON, Government Statist.]

WHEAT, 1933-34—35,373,466bush.; average per acre 9.26bush.

WHEAT, 1932-33—42,429,614bush.; average per acre 10.43bush.

There are still a few minor Wheat Districts where the completion of the collection has been delayed and a number of odd returns from farmers in other districts outstanding, but, rather than further delay the final results, a safe estimate has been made for all these, and hence the totals now submitted may be accepted as final.

1. GROWERS AND ACREAGE SOWN.

Wheat Growers.—There were 14,992 (15,438) Growers of Wheat for all purposes for the Season 1933-34, and of this number 13,970 (14,467) reaped areas for grain. Approximately 1,708 (1,754) reaped areas of under 50 acres. Share farmers counted once only.

Acreage.—The grand total acreage sown to Wheat, Barley, and Oats for all purposes was 4,949,349 (5,039,942) acres, a decrease on the previous year of 90,593 acres.

Wheat.—4,074,417 (4,274,096) acres. Grain 3,821,795 (4,066,782) acres, Hay 246,999 (205,372), Fed Off, &c., 5,623 (1,942).

Barley.—320,527 (322,958) acres. Grain 307,423 (314,286), Hay 2,729 (2,125), and Fed Off 10,375 (6,547).

Oats.—554,405 (442,888). Grain 265,074 (174,244), Hay 247,879 (243,015), Fed Off, etc., 41,452 (25,629).

2. PRODUCTION AND AVERAGES PER ACRE.

Wheat.—35,373,466 (42,429,614) bushels, decrease 7,056,148 bushels, averaging 9.26 (10.43) bushels per acre.

Barley.—5,254,280 (6,070,161) bushels; decrease 815,881 bushels, averaging 17.09 (19.31) bushels per acre.

Oats.—2,087,772 (1,788,712) bushels; increase 299,060 bushels, averaging 7.88 (10.27) bushels per acre.

Hay (Wheaten, Oaten, and Barley).—524,191 (547,060) tons; decrease 22,869 tons, averaging 1.05 (1.21) tons per acre. Distributed as follows:—Wheaten 290,009 (278,875), Oaten 231,607 (265,845), Barley 2,575 (2,340) tons.

3. BENEFITS FROM FALLOWING.

In good seasons the difference in yields per acre of crops sown on fallow and crops on unfallowed land is less than in less favoured seasons, as will be seen from the following return:—

Grown On	Yield Per Acre.				
	1933-34.	1932-33.	1931-32.	1930-31.	1929-30.
	Bush.	Bush.	Bush.	Bush.	Bush.
Fallow	11.60	12.86	14.81	11.05	9.07
Not fallowed	4.78	6.86	7.57	5.48	2.84
Total	9.26	10.43	11.81	8.34	6.40
Rainfall—	Inches.	Inches.	Inches.	Inches.	Inches.
April-Nov.	11.66	14.70	13.27	11.31	9.57

Of last season's Wheat crop 2,508,581 (2,420,674) acres sown on fallow yielded 29,092,873 (31,129,859) bushels, averaging 11.60 (12.86) bushels per acre, and 1,313,214 (1,646,108) acres sown on unfallowed land yielded 6,280,593 (11,299,755) bushels, averaging only 4.78 (6.86) bushels per acre thus making the State average 9.26 (10.43) bushels per acre.

4. SEASONAL CONDITIONS.

Rainfall.—The mean monthly rainfall over the Agricultural Areas of the State is specially computed and recorded in comparison with the averages for the past 29 years. The following are the particulars in inches of the rainfall from April to November for the chief divisions of the State:—

RAINFALL (APRIL-NOV.) AND WHEAT YIELDS PER ACRE.

Year.	Whole State.	Central.	Lower North.	Upper North.	South-East.	West-ern.	Murray Mallee.
	Ins.	Ins.	Ins.	Ins.	Ins.	Ins.	Ins.
Rainfall—							
1933	11.66	14.62	11.32	8.05	15.45	11.71	8.47
1932	14.70	18.39	14.86	9.86	19.68	14.22	11.74
Average 5 years	12.10	15.44	11.42	7.82	18.20	11.27	9.52
Average 29 years	12.73	16.15	12.38	9.03	19.39	11.18	10.53
	Bush.	Bush.	Bush.	Bush.	Bush.	Bush.	Bush.
Wheat Yield—							
1933	9.26	13.85	14.79	6.61	16.14	6.21	5.42
1932	10.43	13.73	15.27	10.77	11.54	6.96	7.68
Average 5 years	9.31	13.69	13.83	7.64	15.03	6.29	6.53

5. THE MARKETING OF THE CROP.

The carry-forward was 1,750,240bush., and with the 1933-34 crop a total of 37,123,706bush. were available. 4,000,000bush. are required for seed and probably 3,500,000bush. for home consumption, including feed for stock and a three months' supply carry forward before the next crop is matured; less this 7½ millions the balance available for export was 29,600,000.

To date of this Bulletin, it is estimated that 10,750,000 has been exported, leaving a balance available for shipping of 19 millions.

It is interesting to record the countries buying the Wheat and Flour, and also Barley, which is now a very useful item of export.

FIVE MONTHS OVERSEA EXPORTS (DECEMBER, 1933, TO APRIL, 1934).

Chief Countries.	Wheat.	Flour.	Barley.
	Bush.	Tons.	Bush.
United Kingdom	5,802,580	12,427	1,145,470
China	—	—	—

Values of Above.—Wheat £1,041,957 (£2,628,063), Flour £144,374 (£190,293), Barley £186,999 (£220,745).

6. AREA INTENDED TO BE CROPPED, 1934-1935.

Particulars have been received from farmers in all Hundreds of the State as to the areas intended to be sown for the 1934-1935 season. These indicate that the Wheat Areas for all purposes will be decreased by approximately 15 per cent. and the Barley and Oaten areas increased, especially the latter.

At a later date information will be obtained as to the actual sowings.

WHEAT, 1933-34—Acres 3,821,795; yield 35,373,466bush.; average 9.26bush.

WHEAT, 1932-33—Acres 4,066,782; yield 42,429,616bush.; average 10.43bush.

ACTIVITIES AT ROSEWORTHY AGRICULTURAL COLLEGE, 1933-34.

PART I.—A GENERAL REVIEW.

[By ALLAN R. CALLAGHAN, D.Phil., B.Sc. (Oxon.), B.Sc.Agr. (Syd.),
Principal Roseworthy Agricultural College.]

INTRODUCTORY.

For several years past College harvest reports have been published annually. These have dealt almost exclusively with results of cropped land, plus certain experimental work on cereal varieties and cereal culture. These records are of particular interest and value. For the year under review, however, a rather more ambitious and comprehensive report is intended, mainly with the object of meeting the needs of the time, and also to make the data which are available of greater general accessibility and interest.

The unprecedented plight of Australian wheat farming has called for a detailed examination of the whole structure of agriculture. The most urgent need of the moment is to reduce costs. Eschewing politics, the agriculturist by surveying the problem in a broad way, realises that costs may best be lowered by the acceptance and practice by the farmer of the most efficient of the existing methods of production, and also by the partial substitution of primary commodity lines less costly to produce.

The metamorphosis characterising the development of agriculture in new lands has proceeded step by step in South Australia, as well as in the wheat lands of Australia as a whole. Speaking in terms of agricultural principles, the pioneer stages of development have passed as far as most districts are concerned. The phase of temporary agriculture, which is both necessary and permissible during the early stages of agricultural development, must give way to a more diversified system. The value of the land is in its productivity, decline in productivity means decline in value, consequently, continuous cropping, or regular cropping in rotation with fallow ultimately reduces the intrinsic value of the land. Continuous cropping—and fallowing falls into the category of cropping, for it is a period when serious calls are made upon the organic matter of the soil for the production of Nitrogen—actually entails a continuous drain upon the resources of the land without any attempts being made at replacement. This type of farming is being followed even in many of the older settled areas of our wheat lands where it is most damaging. I refer particularly to leasehold land which is being farmed to meet the immediate needs of the lessee with no thought of the future value of the land.

The adoption of a system whereby livestock enter into, and become inseparable from, the agriculture of the farm is essential, if the best principles are to be followed. What is more, at the present time, such a system is imperative if the business of farming is to be made profitable and permanent. Such a scheme of affairs does not by any means involve the discontinuance of wheat growing, but it does involve the adoption of wider and more adequate rotations. Under it, every opportunity is given the land to recover; by carrying sheep and other livestock valuable ingredients are returned to the land through their droppings, and organic matter is returned to the soil during the period when the paddocks are resting from cropping and fallow, through the agency of decaying plant tissue.

Apart altogether from increasing the direct returns from their farms under such a system of management, farmers have at their disposal the means of increasing their efficiency as wheat growers, for better yields may confidently be expected.

The Roseworthy Agricultural College farm has been, and is being, farmed along the lines recognised as a permanent system of agriculture, a system which maintains livestock operations as an integral and very essential feature of the cropping and rotational aspects of farming. For this reason a full report of the most outstanding features of the agricultural year must necessarily include reference to, and be co-ordinated with, all lines of activity which are directed towards the livestock carrying capacity of the property.

Additional to this general review there are certain specialised services rendered by the College, such as cereal variety trials, other experimental work and plant breeding, which will receive individual notice under separate reports. Subsequently it is intended to issue all reports as one bulletin.

COLLEGE FARM ACTIVITIES.

The activities of the College farm are very different from any ordinary farm of similar area, and although its management embodies the practice of a balanced system of agriculture, the diversity of its work entails specialised procedure. With a stud of Jersey cattle, a stud of Southdown sheep, stud pigs of various breeds, as well as stud Clydesdale horses, not to mention the various phases of experimental work, the activities combine sidelines of work, seldom if ever undertaken on a wheat and sheep farm.

One of the results of this specialisation in livestock is the retention of much larger quantities of conserved fodder and grain on the place than would be necessary were sheep and fat lamb raising the only consideration outside wheat growing. This must be carefully borne in mind when summing up the position, for much hay and grain, which would ordinarily bring direct returns, is utilised on the farm, thereby inflating the comparative carrying capacity of the property.

By reason of the large number of students in training on the College farm, the assessment of economic values, especially those connected with costs, is an item manifestly difficult. There is a superfluity of labour of variable skill and intermittent energy, the working value of which is well nigh impossible to assess. This is another consideration which complicates the presentation of reports on farm operations from the view-point of agricultural economics.

This review is chiefly concerned with the farming of the College farm for the year covered from the 1st April, 1933, to the 31st March, 1934, and one of the main objects is to bring before the notice of farmers the results which have followed the practice of certain broad agricultural principles.

Without placing undue emphasis upon the diverse and specialised nature of the work conducted at the College, there are several features, vital to the correct interpretation of the farming system in operation, which must be brought into sharp relief. Firstly, there is the rotational system with areas cropped, areas fallowed and areas rested, together with the harvest returns for the year; secondly, the actual carrying capacity of the farm; and thirdly, the returns from sheep with a translation as near as practicable of the possible sheep-carrying capacity. These aspects form part of the general theme of this report, but I do not purpose restricting myself to them: they are itemised merely as focal points for analysis of the data given herein.

GENERAL ASPECTS OF THE YEAR'S OPERATION.

Areas.—The area held by the College covers 2,300 acres, and excluding land occupied by buildings, vines, and orchard, plantations and scrub land, the area of agricultural or arable land embraces approximately 2,000 acres. For the period under review this was occupied as shown below, and illustrated on the accompanying map.

Treatment of College Farm Areas for Period 1/4/33-31/3/34.

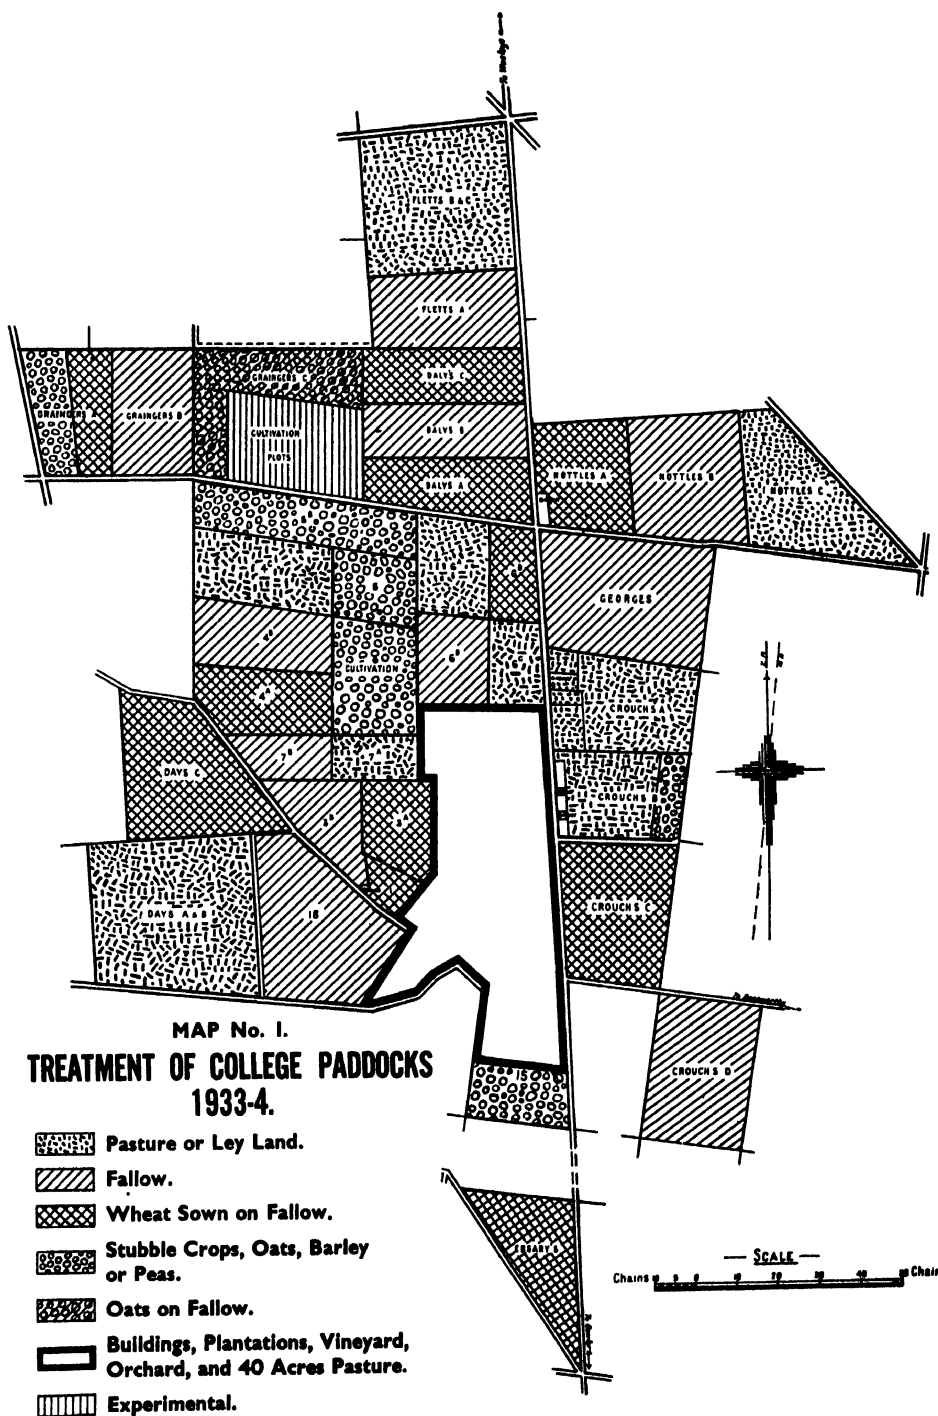

Area fallowed in preparation for 1934 seeding	545 acres
Area rested as pasture (ley land)	595 acres
Area cropped (a) Wheat sown on fallow	532 acres
(b) Oats (122 acres), barley (37 acres), peas (38 acres), ensilage (70 acres) sown on stubble	267 acres
Total Arable area	1,939 acres
Other areas available for grazing	40 acres
Total	1,979 acres

The second map shows the proposed treatments for this year. It will be seen that the normal rotation practised is wheat-pasture-fallow. Variations in the rotations are made in cases where stubble land is cropped, and in some cases the rotation has been wheat-stubble crop (oats, barley, or peas)-pasture-fallow; in one paddock the intention is wheat-peas-oats-pasture (for two to three years)-fallow. This latter arrangement is designed to rest a paddock for a longer period than normally, and periodically every large paddock on the farm will receive a longer pasture term than the one year of the normal rotation. The oats sown following the peas will be sown as a cover crop to a light seeding of Wimmera Rye Grass and Lucerne.

These figures given above indicate that approximately 635 acres were available throughout the year for the grazing of animals, whereas the 800 acres under crop were out of commission for grazing for the greater part of the year and 550 were available only for fallow grazing. The mean number of livestock carried for the period under review was maintained, except for stall and other hand feeding, on these areas. All feed fed to livestock is produce of the College Farm, the only purchases for the year being small quantities of bran for show stock and medicinal purposes. In addition to the arable land mentioned above, small paddocks around the College buildings, amounting in all to about 40 acres, were available to grazing animals, two acres of lucerne were irrigated during the summer and soiled for milch cows and mares with foals, one acre of lucerne was irrigated and used in the poultry run.

Livestock.—The mean numbers of livestock held from the 1st April, 1933, to the 31st March, 1934, are given, together with data relative to their nature and feeding.

The mean number of sheep was 939, and in addition agistment was given 460 wethers for five weeks during the spring. Hand feeding of pregnant ewes and Southdown stud sheep was carried out during February and March of this year, chaff, ensilage, oats, and peas being used in the rations, otherwise the whole of the flocks were maintained by grazing on arable land. During the year 335 fat lambs were marketed and 838 sheep and 104 lambs shorn, yielding 9,355lbs. of wool. The sheep consist of a Southdown stud, Merino and half-bred ewes for fat lamb production, hoggetts, miscellaneous rams for experimental purposes, and ration sheep.

Cattle.—Throughout the year an average of 32 cows in full milk was maintained; this, with an average of 67 dry cattle, including calves, brings the total number of cattle carried for the year to 99. The milking herd is fed daily, and by far the greatest bulk of the feed is ensilage, with oats as the concentrate, but chaff, green lucerne, and some wheat were also fed at different periods of the year. All other cattle during the summer months were fed ensilage in the field; young calves are fed whole milk. The main herd is of Jersey stud cattle, a few half-bred Lincoln Reds remaining in the dry cattle.

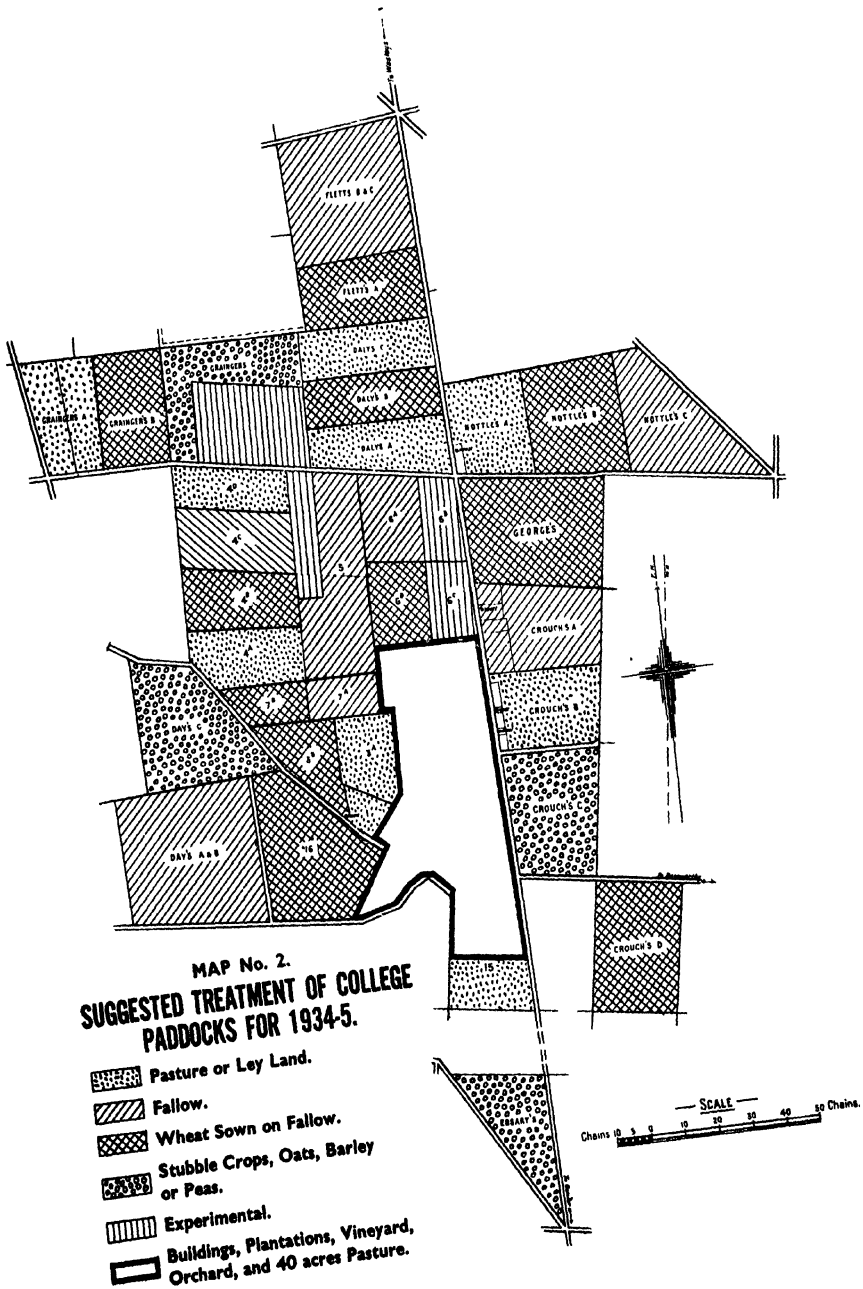

Horses.—The mean number of horses for the year was 78; this includes 58 working horses, a Clydesdale stallion, foals, yearlings, and two-year-olds. The feed is chiefly hay and chaff, with oats as a concentrate during periods of maximum work. Lucerne is fed during the summer to mares suckling foals, otherwise no other footstuffs enter into the regular rations.

Pigs.—With 201 pigs in the swine herd for the year, there is a consumption of large quantities of grain which would otherwise be sold. Skim-milk, wheat, barley, and peas are the foods entering into regular rations, while for experimental purposes green lucerne and meat-meal have been fed. The latter, of course, is not produced on the place and must be purchased. The pigs consist of stud Berkshire, Large White and Tamworths, with various half-bred sows, from which are bred porkers and baconers for the market. The average number of breeding sows maintained for the year was 35.

Poultry.—There were 1,239 birds carried for the year, consisting chiefly of fowls of various breeds, a few ducks, and some turkeys. The poultry are fed chiefly crushed grain, together with green fodder, and for the latter purposes approximately an acre of lucerne irrigated over the summer months.

Considering the pigs and poultry as two means whereby grain produced on the property is marketed, there remain the cattle, horses, and sheep, all of which are dependent upon grazing and fodder produced on the farm. On the average sheep and wheat farm the number of horses required is less and cows and dry cattle need hardly be considered at all. On the basis of comparison these may be regarded as surplus livestock, and they represent a grazing value of approximately 719 sheep. To this there is to be made an allowance for 460 sheep given agistment for five weeks; this in terms of sheep per year amounts to 45. By the adjustments suggested it is possible to arrive at a conservative approximation of the true sheep-carrying capacity of the property last year. The mean number carried was 939, and adding 764 on account of adjustments, brings the total to 1,703 sheep. This represents a carrying capacity of 0.86 sheep per acre, including all cropped areas, and after allowing for sufficient horses to carry out all farm operations.

Harvest Returns.—Having in mind the livestock carried on the farm the harvest returns for last year are the more striking; they indicate, above everything else, that a bountiful season was enjoyed, and taken advantage of. This latter is important, for good seasons are not likely to continue uninterrupted, and if there is one thing I am anxious to draw specific attention to in this report, it is to the fact that a large quantity of fodder was conserved, and that a large proportion of it was conserved from self-sown areas, included in areas set out at the beginning as pasture or ley land. This demonstrates that in spite of the large numbers of stock carried, the season was sufficiently bountiful for one paddock at least to be closed, and its natural growth conserved as ensilage

and hay. It means that in the event of a poor year the advantages of the good year may be more fully utilised, and it acts as an insurance to the carrying capacity of the property. It shows, in other words, that the property was not by any means stocked to its maximum last year, and that the figures stated are fair average of the mean carrying capacity of the farm in all seasons.

The following are the harvest figures for the year:—

HARVEST RETURNS, 1933.

	Total Acreage.	Total Yield.	Average Yield Per Acre.			Mean Yield for 28 Seasons.		
		Bushels.	Bushels.	Lbs.		Bushels.	Lbs.	
Wheat	389	9,675	24	51		17	7	
Oats	83	2,480	29	35		23	21	
Barley	38	826	21	42		24	38	
Peas	38	607	15	50		—	—	
		Tons.	Tons.	Cwts.	Lbs.	Tons.	Cwts.	Lbs.
Hay (crop)	195	430	2	4	19	1	18	85
Hay (self-sown)	40	50	1	5	0	—	—	—
Ensilage (crop)	70	490	7	0	0	—	—	—
Ensilage (self-sown) ...	80	240	3	0	0	—	—	—
Straw (baled)	70	100	1	8	64	—	—	—

The harvest returns, particularly grain yields, were considerably lowered as a result of severe finishing conditions experienced during October, nevertheless the yields compare more than favourably with mean yields. The area harvested for wheat was the largest ever taken off at the College in one year, and only on two occasions previously has the average yield of 24bush. 51lbs. been exceeded, once in 1909 by 14lbs. and again in 1920 by 1bush. In other words the average yield this year was only 1bush. off the record and it was 7bush. above the average. This is the more significant when it is recalled that in the two years 1909 and 1920, the rainfall recorded was well above average, being 24.05in. and 19.30in. respectively, whereas, in the year just closed the rainfall of 16.85in. was below the average, which for the past 51 years is 17.52in.

Summating these figures to crystallise them, it is found that from the total of 930 acres harvested 13,588bush of grain, 480 tons of hay, 100 tons of straw, and 730 tons of ensilage were harvested. Superimposing the data given concerning the livestock carried, and making very liberal allowances for the conditions under which they are kept at College, the results are at least arresting.

Balance of Production and Consumption.—The following table is compiled to indicate the reserves on hand, and also to show the quantity of produce available for sale.

Feed.	Fed to Livestock, 1933-34.	Harvested, 1933-34.	Carried over from 1932-33.	Carry over for Sale and Reserves from 1933-34.
	Bushels.	Bushels.	Bushels.	Bushels.
Wheat	3,840	9,675	2,924	8,759
Oats	2,051	2,480	1,148	1,577
Barley	1,130	826	720	416
Peas	315	607	297	589
	Tons.	Tons.	Tons.	Tons.
Chaff and Hay ...	547	480	618	551
Ensilage	445	730	255	540

On the basis of last year's production and making due allowance for seed wheat for this year's seeding, a little more than 5,000 bush. of wheat are available for sale. Practically all the other produce is fed to animals and marketed in this way or else it is held in reserve for feeding purposes.

Fat Lamb Production.—One of the most remunerative of College activities is that of fat lamb production, and as this enters into the possible scope of a wheat and sheep farm a few figures bearing on the work at College last year should be of interest. Last year experimental work with the Border-Leicester-Merino flock reduced the percentage of lambs and the total numbers, but from the point of view of returns a substantial improvement was noted.

PARTICULARS OF LAMBING, 1933.

Breeding of Ewes.	No. of Ewes Mated.	Deaths before Lambing.	No. of Ewes Lambing.	Rams Mated.	Lambs Marked.	Lambing Percentage.	Remarks.
Merino	99	2	97	Border-Leicester	94	97	Neither group interfered with by experimental treatment—Average, 102% Twin Lamb Disease Investigation.
Merino	25	1	97	South-down	104	107	
Dorset-Merino	73						
Corriedale and English Leic.-Merino	40	4	36	South-down	21	58	Ewes kept enclosed in a small yard on chaff feed. Many dead lambs taken away from these ewes.
Merino	60	9	111	South-down	102	92	Drought feeding Experiment 9 ewes died with (T.L.D.) before lambing and 8 lambs died before marking.
Dorset-Merino	60						
Border-Leicester-Merino	25	1	24	Dorset .	24	100	These ewes were mated in separate flocks of 25 (to one ram) which accounts for the low percentage in some cases.
	25	—	25	Suffolk ..	17	68	
	25	—	25	Ryeland .	8	32	
	25	—	25	Shropshire	10	40	
	25	1	24	South-down	18	75	
Total . . .	482	18	464		398	86%	

A report on the feeding trials has already been issued and details of the fat lamb breeding experiment will be recorded when the results from this year's matings are available.

The total number of fat lambs marketed last year was 335 and the average net return was 16s. 3d. per head. Of this total 156 were marketed at the Abattoirs with an average net return of 15s. 4d. per head, whereas 142 lambs exported direct returned 17s. 10d. per head net. In addition to this, by private sale of reject and other lambs 37 were disposed of to return 13s. 8½d. per head net.

Five consignments of lambs were entered in Export Competitions. The first consignment by Southdown out of Dorset Horn-Merino half-bred ewes was successful in winning the Cooper Cup for the best entry of lambs exported from South Australia in 1933.

SUMMARY.

1. The Roseworthy College Farm has been, and is farmed with the object of maintaining soil condition and the productivity of the land.

2. A more diversified system of agriculture is developing in the agricultural areas, and livestock is entering more largely into the management of most farms.

3. Out of total arable area of approximately 1,950 acres, 550 acres were fallowed, 600 acres were rested as pasture or ley land, and 800 acres were under crop.

4. During the year the livestock carried consisted of 939 sheep, 99 head of cattle, including 32 cows in milk, 78 horses, 201 pigs, and 1,239 head of poultry. No feed other than small quantities of bran and meat meal was purchased, and the livestock were maintained on the property by grazing and feeding of fodder produced on the place. Excluding horses necessary for farming operations, the pigs and the poultry, the equivalent sheep carrying capacity of all areas including fallow and crop amounted to 0.86 sheep per acre.

5. From cropped areas and the produce of one self sown paddock, 13,588 bush. of grain, 480 tons of hay, 100 tons of straw, and 730 tons of ensilage were harvested.

6. During the year 335 fat lambs were sold locally or exported at the average net return of 16s. 3d. per head. The average net return for lambs sold through the Abattoirs was 15s. 4d., for those exported direct the average price was 17s. 10d.

BOTFLIES.

Replying to the Secretary of the Elbow Hill Agricultural Bureau, who asked for the best treatment for botfly grub in horses, Mr. R. H. F. Macindoe, B.V.Sc., M.R.C.V.S. (Deputy Chief Veterinary Officer) says although the majority of horse-owners hold the opinion that the botfly grub found in the stomach is injurious to the animal's health, this view is contrary to fact. While it is admitted that occasionally an animal may die through an impaction of the stomach due to the interference with movement of food from the stomach into the intestines, such cases are exceptional, and the grub does little harm when one realises how prevalent the insects are, for practically all horses harbour them.

To get rid of them is by no means easy, and treatment is, generally speaking, unsatisfactory, as the grubs are very resistant to the effects of most drugs.

If medicinal treatment is attempted, the best drug for the purpose is carbon bi-sulphide, which is a liquid, and administered in gelatin capsules, each containing 2-3 drams. The routine treatment is as follows:—Keep the horse without food for 12-20 hours, then give 1 capsule; after an hour, give a second capsule; and after another hour give a third capsule.

As carbon bi-sulphide is strongly irritant, very great care should be taken in the administration, to see that the cap of the capsule does not come off, or that the horse does not crush them in the mouth.

Although this treatment is the best, it is not recommended for general use by the horseowner himself, owing to the danger of injury which may occur to the membrane if the capsules should break.

Another treatment is tincture of iodine $\frac{1}{2}$ oz., administered in a capsule 4-5 mornings in succession, and about two hours before feeding, the last dose to be followed by a drench of raw linseed oil, 1 pint; oil of turpentine, 4 tablespoonsful. The best time to treat horses varies in different localities, but usually the best time would be between March and May.

THE SELECTION AND TREATMENT OF FRUIT TREES AND VINES IN THE HOME GARDEN.

(Wireless Address by R. FOWLER, Manager Blackwood Experiment Orchard.)

The foundation of a successful fruit garden lies in the careful preparation of the soil before planting. In a test set out for the purpose at the Experimental Orchard at Blackwood it has been proved that it pays to subsoil the ground before planting, so that in the preparation of a garden I would say, if possible have the soil broken up to a depth of 12in. to 18in. either with horse implements, or else trench or deep dig it by hand. If this is not possible over the whole area a strip say 6ft. to 8ft. wide where the trees will stand might be done, and failing this, then a hole approximately 4ft. x 4ft. should be made.

In all of these operations the subsoil should be broken up well, but not brought to the surface. When digging the holes the surface soil should be removed, say, to the depth of 9in., the subsoil well loosened to the depth of another 9in., but not removed, and if manure of any sort is to be used, it should be well mixed up with the subsoil. By breaking ground up as suggested, it enables the root system of the tree to penetrate freely to a depth that will not be subsequently rapidly affected by heat or cold. It is not advisable to dig large deep holes, particularly into stiff clay subsoils, as the tendency then is for the water to drain into the hole, and trees cannot thrive except in well-drained situations.

When planting, the tree should not be placed at a greater depth than it stood in the nursery, as indicated by the soil mark on the bark. It should be firmed in well, starting from the outside of the hole and working in to the centre, and when finishing, the earth should be heaped up to the tree trunk to a height of 1in. to 2in. above the ground level to allow for subsequent sinkage.

It is not advisable to have the surface immediately surrounding the tree lower than the ground level, as this acts as a basin for collecting surface water, and will cause the loose soil to become sodden, a condition very detrimental to the young tree.

Before planting, injured or damaged roots should be trimmed with the secateurs, and when planting, the roots should be carefully spread out, so that the tree will be well braced from all sides, and not liable to be blown over.

Generally the best time to plant deciduous fruit trees in this climate is during early winter after a good soaking rain. The soil will still be warm and the roots will send out fresh fibrous roots to replace those torn off and injured, even while the top portion of the tree is quite dormant.

A series of tests carried out in the Experimental Orchard have proved that trees planted in May make quite a considerable amount of root growth during the winter months where the soil conditions are favourable.

If manure is to be applied, and it is generally a good plan to give the tree a little assistance in this manner, it should be well mixed with the subsoil before the tree is planted, in the case of farm or stable manure or bonedust. If sulphate of ammonia is used, it should be well mixed with the surface soil. The amount of manure to be used might vary with the quality of the soil, but as a basis to work upon I would suggest for farmyard manure 4 to 5 good shovelful of well-fitted manure, for bonedust 1lb., or roughly 2 to 3 double handful, and for sulphate of ammonia 3ozs. to 4ozs. Each tree should be tied to a stake, driven down before planting, to protect the tree from injury during tillage operations the first couple of years. If conditions are dry at the time of planting, an irrigation should follow, and during planting operations the roots of the trees should not be unduly exposed to the sun.

The distance apart will, to a large extent, depend on the size of the home garden and the number and variety of the trees to be planted, but as a general rule 16ft. to 18ft. apart is close enough, though under most orchard conditions

trees are planted 20ft. apart. They should be kept at least 8ft. or 10ft. away from the surrounding fence, and where this is of palings or iron, it affords good shelter without removing moisture or plant food. A shelter of some kind is necessary, and failing the regular fence, a hedge of some sort—Carob, Tagosaste, or Kaffir Apple is suggested.

In selecting the young trees from the nursery, it is well to avoid very large trees, which are probably two or three seasons old, and to select those of one season's growth from the bud, carrying well-ripened, short-jointed wood, with plump, well-defined buds.

Soon after planting, but not before, the young trees should be pruned, cutting out the centre, if the tree is already headed, to give an open framework, leaving four or five leaders in the case of peach and apricot trees, cutting generally to an outside bud, so that the subsequent growth will tend to keep the tree open. The reason for not pruning before planting is that the terminal buds may be injured in the process of planting, and in addition, a better idea can be formed of the placing of the limbs and selection of terminal buds.

In deciding which varieties to plant, the commercial grower has to be guided by the future markets for his produce, whether it is to be sold locally fresh, canned, or dried, or exported to overseas markets. No such considerations affect the home garden. Here it is a question of good fruit for eating and preserving, and in some cases drying, and a continuity of supplies, that is, varieties so arranged that as one finishes another will be coming on, and not a glut at one period and no fruit at another.

In the following lists of varieties I have endeavoured to arrange them so that there will be little overlapping:—

Apricots.—Oullin's Early, Moorpark, Late Riverside.

Peaches.—Wright's Early, Wiggins, Peregrine, Louis Grognet, Finlayson's Seedling, Prizetaker. Canning—Elberta for freestone or Golden Queen for clingstone.

Nectarines.—Dr. Chisholm, Goldmine, New Boy, W. C. Fripp.

Plums.—Angelina Burdett, Early Orleans, Grand Duke, Greengage, Jefferson, Prune d'Agen. Canning—Coe's Golden Drop, Jefferson, and Greengage.

Plums—Japanese.—Formosa, Burbank, Climax, Santa Rosa, Rubio, and Wickson.

Almonds.—Hatch's Nonpareil (subject to gumming), Ne Plus Ultra, Jose's B1, Peerless, Chellaston.

The above lists contain probably many more varieties than could possibly be planted in the home garden, and from these I would select the following twelve:—

Apricots (2)—Oullin's Early, Moorpark.

Peaches (3)—Wright's Early, Louis Grognet, Elberta.

Nectarines (2)—Dr. Chisholm, Goldmine.

Japanese Plum (2)—Climax, Wickson, or Santa Rosa.

European Plum (2)—Angelina Burdett, Jefferson.

Orange (1)—Washington Navel.

Lemon (1)—Lisbon.

If more space is available, I would plant a Persimmon (Kurokumo or Jubilee) and a Loquat (Sewell's Enormity). The Almonds would be planted probably along the back fence, and any of the varieties mentioned could be selected.

The laying out of the garden gives room for individual taste, and no set plan can, therefore, be advocated, but I think it is a good plan to group your trees to the best advantage in the ground available, and plant vines so that they can

be grown with the fences acting as a trellis. In this position they are out of the way, and do not interfere much with the general lay out. Trees and vines should not be interplanted.

Having now dealt with the preparation of the soil, and the selection of the trees, we come to the subsequent treatment.

Remember that the first few years are the most important to young trees. If at this stage they are neglected and allowed to become stunted, they have very little chance afterwards of making successful trees, and it is mostly on good cultivation that their future successful growth depends.

It is not enough to prepare the ground, dig a hole, put the trees in, and then leave it for the rest of the season. The planted portion of the garden should be thoroughly tilled during the summer months, the hoe and the fork should be kept going, so that the young tree will get a decent chance, and it will repay for the time and attention given to it.

For the first few years vegetables, particularly root crops, can be grown between the trees, and to some extent later on, if the ground is well treated with manure, but trees and vegetables, as a rule, do not thrive well together.

My remarks so far have applied to deciduous trees—those which lose their leaves in winter—but different treatment in some particulars is necessary for citrus trees, orange and lemon. The time for planting these trees is in the early Spring, about September or October, just when they show signs of returning growth. If planted now, there is a danger of the young growth, which these trees frequently throw out after being transplanted, being cut by frosts.

They need pruning rather severely after being transplanted, if the root system has been mutilated or dried up. It is well to see that the roots of young citrus trees are not exposed to the air at all before planting, and nurserymen, as a rule, send out these trees with a ball of earth attached wrapped round with a piece of hessian or bagging. This need not be removed when planting, as it will soon rot in the soil. Citrus trees need protection from wind, and it is well to provide this in some way. A thin covering of straw wrapped loosely round each stem is a protection from the sun if the pruning has unduly exposed the bark, and will be found an advantage. Citrus trees, being evergreens, will require more water than deciduous trees, and careful attention must be given

The AVERY Rabbit Exterminator

(PATENTS PENDING—Numbers 4387-31. 6867-32.)

Is a light, self-contained outfit which forces dense volumes of smoke and poisonous carbonaceous gases into the warren. The operation of the "AVERY" Exterminator is simple, safe, and inexpensive, as the poisonous gases are scientifically produced by using only damp straw or grass, etc., supplies of which are available on every farm and station.

For prices and full particulars write to

to this, but that does not mean that they should be overwatered. The soil should be kept moist, but well drained, and not allowed to become water-soaked or sodden.

PESTS AND DISEASES.

The most troublesome fungus pests likely to be found will be the *Curl Leaf* of the peach and *Shothole* of the Apricot, Almond, and Japanese Plum.

No doubt *Curl Leaf* is familiar to all peach growers, and its characteristic appearance on the trees well known. It is not as destructive in the drier parts of the State as it is in the moister districts, but it should be guarded against. It is caused by a fungus known as an internal fungus, that is, the mycelium of the disease penetrates into the leaves, and once inside cannot be reached by any spray mixture. The spores, or what might be termed "seeds" of the disease, pass the winter somewhere on the tree, mostly about the buds, and commence their active growth just when the tree itself commences to burst into bloom. It is at this time that spraying for this disease should be done at what is called the "pink" stage of the bud. If delayed until the leaf buds are well developed, the disease will have found entrance into the leaves, and it cannot then be checked, so that it is quite useless to spray peach and nectarines trees after the disease once appears on them. Generally, the effect then is that the diseased leaves will eventually curl up and fall off, and if the attack has not been severe, little injury may result, but sometimes trees are so badly attacked that most of the first leaves fall off, and before the second leaves come the fruit also has fallen off. Very often the fruit itself is attacked by the disease. The remedy is to spray at the right time, that is, the "pink" stage of the blossom buds, with Bordeaux or Burgundy Mixture.

Shothole of the apricot and almond is also a fungus disease causing considerable damage at times. The name is derived from the characteristic round holes which appear in the leaves, much resembling small holes that might have been caused by shot from a gun. The holes are the result of injury caused by the disease affecting that portion of the leaf.

The treatment is the same as that for *Curl Leaf* of the Peach, and should be done at the same time, and with the same mixture, but the application is sometimes repeated with a certain amount of benefit if the disease appears badly on the trees at a later period, but generally, one application in the Spring is enough, especially if an autumn spray has been applied. It is of benefit to spray during May with Burgundy or Bordeaux Mixtures to destroy the winter spores.

European Plums may also be affected with *Prune Rust*, another fungus disease, but the attack generally comes so late in the season that little harm results.

Insect pests are likely to be *Black* and *Green Aphis* of the Peach and Japanese Plum and *Red Spider*, particularly on the Almond, and *Curculio Beetles*. The best remedy known for aphides is Nicotine Sulphate or Black Leaf 40. This can be procured in small quantities, and though expensive, a little goes a long way. It is used at a strength of 1 pint to 100 gallons of water, with the addition of 4lbs. of soft soap. Directions will be found on the container. As all the Aphis family increase at an enormous rate, it will be found necessary to spray every few days for a short time, until the pest is well under control. Generally aphides disappear when the very hot weather commences. A winter spray with a Red Oil emulsion or Tar Distillate also helps in the control of these pests, and with Red Spider as well. Red Oil or Tar Distillate cannot be used in the summer. They are strictly dormant period sprays.

For *Red Spider*, Lime Sulphur Spray in the summer is very effective, but should not be used stronger than 1 part solution in 70 parts of water.

Curculio Beetles are very difficult to control, but sometimes 1lb. of Arsenate of Lead to 8galls. of water proves effective. Other methods are trapping, bandaging with wool, etc.

IMPORTANT WEEDS OF SOUTH AUSTRALIA.

[By G. H. CLARKE, B.Sc., Botanist at the Roseworthy Agricultural College.]

No. 6.—STINKWORT.

Inula graveolens, Desf.

Stinkwort is said to have first made its appearance in Australia some seventy years ago in the Onkaparinga district of this State, and though efforts were made by many farmers to keep it within bounds during the early years following its introduction, it gradually spread, and has since become firmly established throughout all the agricultural areas of the State. To-day it is probably the most widely spread weed in South Australia, besides occupying large areas in Western Australia and Victoria, and somewhat smaller areas in New South Wales. Reaching its greatest development during the late summer and autumn months, Stinkwort covers hundreds of acres with a vivid green growth, which contrasts sharply with the prevailing straw-like colour of stubble and grassland, and with the chocolate-brown tints of fallowed ground. Seen from the distance it creates an illusion of luxuriant pasture on land often quite barren of any other kind of green herbage. The plant is so firmly established here that it would be futile to place it upon the list of proclaimed noxious weeds, but this does not mean that, by proper management of the land, an intelligent farmer cannot do much towards keeping his property free of this particular weed.

Stinkwort owes its popular name to the presence of a resinous oil with a strong and characteristic odour. This oil is an external secretion formed by innumerable small glandular hairs present on all parts of the plant's surface. Under a microscope these hairs appear as blunt finger-like papillae which arise from the epidermis or covering layer of cells. Owing to this secretion the surface of the plant is very sticky so that particles of dust, &c., readily adhere to it, which accounts, in part, for the dirty green colour of many specimens. The wool of sheep pastured on Stinkwort country is greatly discoloured, but its quality is not impaired, the colour being easily restored in the scouring process. Milk and butter are tainted if dairy cows are permitted to eat the weed, and the flavour of mutton may be affected if sheep are fed upon it.

In outline the plants are roughly conical, and are somewhat suggestive of miniature cypress pine trees. They have an erect, much-branched habit, the lateral branches arising from a stout central stem and branching again and again so as to form a diffuse system. All the stems bear slender leaves and very numerous small ovoid heads of yellow florets surrounded by greenish-coloured bracts. When mature these heads appear as fluffy balls due to the development of a tuft of hairs on each of the contained "seeds" or fruitlets. The weed shows a decided preference for cultivated land, but is often abundant along the roads, especially where the plough is regularly used to clear the roadsides of noxious weeds. A particularly dense growth of Stinkwort is often seen on land cultivated only at infrequent intervals; such land may be completely covered with a forest-like growth of crowded plants.

Botanical Name and Classification.—*Inula* was the Latin name for Elecampane (*Inula Helenium*, L.), which was formerly used in medicine, and is said to be still used to some extent in veterinary practice. The species name *graveolens* means "strong-smelling." Like the thistles and Bathurst Burr the *Inulas* are members of the *Compositae*, but they belong to a distinct tribe of that large and important family. This tribe (*Inuleae*) includes, among others, many species of so-called "everlasting" flowers. The genus *Inula* comprises about 100 species belonging

Stinkwort, showing general habit (see coloured plate opposite).

STINKWORT (*Inula graveolens* Desf.)

A.—"Seed" with pappus. B.—Upper leaf, entire and nearly linear. C.—Lower leaf, oblong-lanceolate and sub-dentate. D.—Flower-head, passing into fruit. E.—Staminal tube opened out showing tailed anthers. F.—Female ligulate floret. G.—Bisexual tubular floret. H.—Single head showing bracts and florets.

to Europe, Asia, and Africa, the best-known species being *I. Helenium* or Elecampane, of which a decoction of the root was formerly used as an aromatic tonic. The *Inulas* are mostly herbs with alternate leaves. The flower-heads may be solitary or numerous, and contain florets of two kinds enclosed within an involucre composed of numerous bracts arranged in several rows. These bracts are usually green in *Inula*, but in certain other genera of the same tribe they are brightly coloured and simulate petals, except for their tougher consistency and resistance to drying, the whole flower-head, in such cases, giving rise to the structure popularly termed an "everlasting" flower. Within the involucre the florets are arranged in two series. There is an outer series of "ray" florets in which the corolla is strap-shaped or "ligulate," and from which stamens are missing, and an inner series of "disc" florets in which the corolla is tubular and stamens are present. The anther of each stamen is prolonged at the base into two long appendages or "tails." The fruitlets are small and cylindrical, and are surmounted each by a pappus of fine silky hairs.

Description of Inula graveolens.—A sticky herbaceous annual with a strong odour, glandular-hairy all over, 1-2 ft. high; stem erect, much branched, with erect spreading leafy branches; lower leaves oblong-lanceolate and subdentate, the upper ones linear and entire. Heads small, very numerous, subsessile, in a long loose pyramidal panicle; involucre bracts in several rows, linear lanceolate, the outer ones green, the inner ones with scarious margins; florets yellow, the outer ones ligulate and female, slightly exceeding the involucre, the inner ones tubular and bisexual; anthers tailed; achenes hairy, narrowed into a neck at the summit, then expanded and supporting the pappus of numerous barbed capillary bristles. Period of flowering: March-April.

Properties.—Few weeds have given rise to as much discussion and difference of opinion among farmers and stockowners as has been the case with Stinkwort. To some it is a useful fodder plant, present in great abundance at a time when other green feed is scarce, while others regard it as a weed, objectionable in many ways but not seriously harmful, either to stock or to the productivity of the land on which it grows; others, again, are of the opinion that Stinkwort is poisonous to stock, at least during its flowering and fruiting stages. While there is no doubt that the State would be much better off without the plant than with it, it is not as serious a pest as has often been supposed, despite the very dense growth it makes on certain areas during the summer months.

Firstly, as regards its effects on stock, at no stage does the plant appear to be actually poisonous in the sense that some other plants are. It does not contain any poisonous alkaloid or other toxic principle capable of causing death when introduced, in relatively small amounts, into the body of an animal. During the young stages stock will and do eat it without harmful effects, and feeding tests, both here and in other States, have failed to prove that the plant is poisonous even when mature. In these tests sheep have been fed with the fresh plants, or drenched with extracts, both types of experiment invariably yielding negative results. On the other hand it is well known that mortalities have occurred among sheep pastured on Stinkwort country, and without having had excess to other green feed, especially during March and April, when the plant is in flower, and when other green fodder is scarce. The intake of large amounts of Stinkwort, especially when wet with rain or dew, may lead to a condition of bloat, but the same is liable to occur with other fodders, even with lucerne, and is in no way peculiar to Stinkwort. But the weed may be dangerous in another way; the full-grown plants contain a large amount of woody fibre which, if eaten in quantity by hungry or travelling stock, may cause digestive troubles due to mechanical irritation of the stomach and intestines. Moreover, the mature plants bear fruiting heads in countless numbers, each composed of a large number of fruitlets armed with barbed hairs. Sheep, feeding upon Stinkwort at this stage, cannot avoid taking in large amounts of such indiges-

tible material, which is liable to produce irritation and inflammation of the digestive tract, and so render the system subject to attack by bacteria present in the intestines, and facilitate the absorption of their toxins. Braxylike disease, which is caused by a specific bacterium and is at times responsible for deaths among stock, often affects sheep on Stinkwort pastures, and the opinion has been expressed by veterinary officers that this plant may be a predisposing factor in braxylike disease. This does not prove, however, that Stinkwort is poisonous; it merely shows that, by causing acute intestinal disturbance, it may render animals liable to attack by disease-producing bacteria.

The spoiling of milk and butter as a result of the ingestion of Stinkwort by dairy cows has already been mentioned. The resinous secretion has an irritant action on the skin to which some persons are peculiarly susceptible. Cases of dermatitis have been known to occur among those engaged in hand-pulling the weed, an operation which should not be undertaken without using gloves. The role of this secretion in the physiology of the plant is not quite clear. Formed externally, and becoming concentrated by evaporation of its more volatile constituents, it may possibly play a part in checking transpiration losses, and in reducing the effects of prolonged and intense irradiation. Or it may serve to protect the plants against parasitic infection; that the oil may have some influence upon bacterial activity is suggested by the slow decay of the plants in the soil, and by the possible role of Stinkwort in braxy-like disease.

From the wheatgrower's point of view Stinkwort is not as troublesome as weeds which develop later in the year. It is a summer weed, and has practically finished its growth at seeding time, and the seeds, though present in great numbers in the soil, do not germinate until after the harvest has been taken off. Being a rather deep-rooted annual it is of some value in opening up and aerating the soil, particularly in lands with a heavy clay subsoil. On the other hand it dries out the soil, and, by its slow decay, creates difficulties in working the ground.

Eradication.—Notwithstanding the wide distribution of Stinkwort, it is a striking fact that certain areas are comparatively free from it, even in districts where the weed is especially bad. While it does not spread much on uncultivated land, neither is it troublesome on land that is regularly cultivated, manured, and cropped. It makes its greatest growth on land which is infrequently cultivated, seldom manured, and cropped only at irregular intervals, all of which shows that, by proper farming methods, much can be done to keep wheat land free of this as of other weeds. There may, however, be another factor at work. Stinkwort seems to thrive best on land to which phosphatic manures are seldom applied, and which, presumably, are deficient in phosphates. At the present time the Roseworthy College farm lands are singularly free of Stinkwort, though, according to the statements of former students, the weed was plentiful at one time and, in fact, is still plentiful in the district. It has been suggested that the changed state of affairs is to be attributed to the regular use of superphosphate, which may thus prove to be a valuable and economical means of control, inasmuch as, the manure being paid for by improved yields, the cost of eradication would be comparatively small.

Since the weed is readily eaten by stock during the young stages, the stubble should be heavily grazed by sheep immediately after harvest. By this means a dense growth of the Stinkwort is very largely prevented. If possible the plants should not be allowed to form seed, and should be ploughed up before they come into flower. Small patches of the weed should be hand-pulled and burnt.

THE BAKING QUALITY OF AUSTRALIAN WHEATS.

No. 2.—THE QUESTION OF QUALITY AND THE PELSSENKE TEST.

[By A. R. HICKINBOTHAM, B.Sc., Dip. Ed., A.A.C.I., Chemist,
Agricultural College, Roseworthy.]

[The following article is the second of a series which was commenced by Dr. Callaghan in the May issue.]

INTRODUCTION.

With few exceptions, the wheat grown in South Australia is consumed as bread and, therefore, the value of any sample or variety of wheat depends primarily on the kind of bread that can be made from it. In addition to this fundamental requirement, a variety of wheat should possess other features to satisfy the special demands of each person who handles it. The grower likes to produce a nice, plump, even sample, but he must obtain a high yield per acre; the miller wants grain of easy milling qualities that will give him a high percentage of flour; while the baker requires the flour to handle well in the bakehouse, and give him a large number of loaves from each sack.

Because so many interests are concerned, each with special demands, it has proved to be an extraordinarily difficult thing to obtain a clear and concise definition of the term "strength," but in seeking such a definition it is necessary to recognise that the consumer, after all, has the last say, and the baker, the miller, and the farmer must ultimately judge their products from the consumer's point of view. A variety of wheat may, however, have desirable qualities from several points of view. Those varieties which are recognised as being of really high quality, or "strong," generally satisfy all demands except, unfortunately, that of the grower; under local conditions the definitely high quality wheats at present available do not yield well. On the other hand, low strength wheats yield well

Roseworthy Agricultural College.

Annual Winter School for Farmers, 1934.

The Annual Winter School for Farmers will be held at Roseworthy Agricultural College from the morning of the 8th August to the morning of the 17th August.

A comprehensive course of lectures and demonstrations is being arranged. The Minister will open the School on the 8th August, and Mr. McCann, the S.A. Trade Commissioner in London, who is at present visiting South Australia will lecture the School. Others lecturing the School include the Director and members of the Waite Institute Staff, Officers of the Department of Agriculture and the Principal and Staff of the College.

Arrangements with outside lecturers are not yet complete.

Conditions for enrolment have been circularised to all branches of the Agricultural Bureau; non-members of the Bureau will be supplied with these on application.

ALLAN R. CALLAGHAN, Principal.

and may mill well, but they generally fail to satisfy the handling requirements of the baker; they always produce an unsatisfactory loaf lacking in shape, bulk, and appearance, and in attractiveness to the consumer. Flour of very low strength is necessary for making biscuits and certain types of cakes, and sometimes wheat is grown specially for this trade. Such samples are obtained where a very long ripening period is experienced, and are well suited by conditions in Tasmania, but the climate of most of our wheatgrowing areas is obviously unsuitable for them.

Australian wheats have always had the reputation of being of relatively low strength. When flour was first milled here, wheat was imported from America and blended with locally grown samples for the purpose of improving the strength of the flour, but it was found that the practice met no special demand, and it was soon discontinued. The earliest plant breeders also recognised this weakness, and sought to produce new varieties that would yield a strong flour, but their experience soon indicated that it was extremely difficult to combine high yielding capacity and really good quality or strength in one variety. In the pioneering stages high yield per acre and drought resistance were of fundamental importance and so, for many years, strength received little attention. From time to time efforts were made to revive interest in this question without success, but lately it has been brought prominently before the public because of adverse criticism by overseas buyers who maintain that there has been a drift in quality in recent years. Without doubt, this position has arisen partly because of changed conditions in the handling of flour in bakeries where machinery has largely displaced hand work, but it is also said to be partly due to a falling off in the quality of our bulk wheat through the introduction of new varieties of lower strength than those they have displaced. This latter contention appears to be justified in only a few cases, but in a period of over-production particularly, any falling away in quality must influence the demand and the price received for our wheat. On the other hand, an increase in strength would widen its range of usefulness, and be reflected in a greater demand and, ultimately, in better prices.

COMPOSITION OF GRAIN AND FLOUR.

A wheat grain consists of three main parts: the germ or embryo, the starchy centre or endosperm, and the covering or skin. In the process of flour making, the germ is removed because it contains oil which would go rancid and spoil the flour, while the skin yields bran and pollard. The centre portion or starchy endosperm is ground into flour, this product forming about 70 per cent. of the grain. If the grain is small, or thick skinned, the proportion of skin or bran is higher, and less flour is obtained from each bushel, so that a large, plump grain is desired.

Flour contains three important constituents, namely, starch, protein material, and sugar. Starch constitutes about 90 per cent. of the flour, and confers on it most of its food value but, though it forms the bulk of the loaf it is of small importance in baking. The protein material consists of nitrogenous substances, and gives rise to gluten in the dough; it is present in the grain as a network of threads throughout the starchy centre of the grain, and forms about 10 per cent. of the flour. The sugar, which forms approximately 1 to 2 per cent. of the grain, serves as food for the yeast which converts it into alcohol and carbon dioxide gas, and it is the formation of this gas that makes the dough rise. Australian flours are generally low in sugar but, if there is a deficiency in the flour, it can be added in making the dough, so that the actual quantity in the grain or flour is not of great importance.

GLUTEN.

The important constituent in bread making is the gluten, and each variety of wheat tends to have a characteristic amount of gluten of a good or bad quality. A large amount of good gluten allows the dough to absorb more water, and there-

fore makes more loaves from each bag of flour. It enables the loaf to stand up well, and hold more of the gas formed by the yeast, so that the loaf is larger and looks better, and it confers on the bread a more silky texture and resilient crumb. Further, it causes the dough to work easily, making it tough, elastic and non-sticky, and it permits the baker to mishandle the dough to some extent without appreciably spoiling the loaf, a point of considerable importance in bakeries where machinery is extensively used.

Gluten may be separated from wheat by chewing; it is obtained as a substance like chewing gum which is essentially *wet gluten*. If placed in a warm place such a plastic piece of wet gluten would dry out forming a horny piece of *dry gluten* weighing about one-third of the weight of the wet gluten. The great amount of water that gluten may absorb, without becoming sticky in many cases, is an important characteristic of this substance, and it varies to some extent in gluten from different varieties.

QUALITY AND STRENGTH.

Bakers and millers use the term *quality*, but more usually *strength*, to denote certain characteristics in flour, but it is by no means easy to define strength concisely. The word is used to distinguish contrasting types of flour. One sample will take a lot of water forming a tough, elastic, resilient dough which is easy to handle and bakes into a large, bold, upstanding loaf having a fine, even, silky texture. At the other extreme, another sample of flour will absorb appreciably less water giving a soft runny dough that is difficult to work, and that bakes into small loaves of uneven texture, the comparatively dense bread being broken by large, irregular cavities. The former is obviously the more desirable, and flour giving that type of loaf is called *strong*, and the wheat from which it is made is a *strong* or *high quality* wheat.

The definition usually adopted by cereal chemists is:—*That a strong wheat is one which yields flour capable of making large, well-piled loaves.* In this definition the word "pile" has a special significance, being applied, not to the shape of the loaf, but to the texture of the loaf when pulled apart—it should be of a smooth, even, silky texture recalling the pile of velvet. The definition has been subjected to some criticism for it implies that the size of the loaf is the main indication of strength and, since size can be measured accurately and other factors are often difficult to evaluate, there has been a tendency to over-emphasise its importance for this purpose, and to neglect textural and working qualities which a strong flour should also possess.

THE MEASUREMENT OF QUALITY.

The only conclusive test of quality is a good loaf and, as a rule, the baking test is used to determine the quality of the flour of any variety of wheat. In this test the wheat is milled, the dough made and the loaves baked under standardised conditions, and the quality of the flour is determined by loaf measurements and, generally, the allotment of points for each of the important characteristics of the loaf and perhaps, also, of the dough. In many procedures the best result is sought in every case, so that the composition or treatment of the dough may be varied to attempt to correct the weaknesses thought to be present; further, the assessment of the value of the loaves is generally left to some extent to the personal judgment of the baker. Consequently, the experience and skill of the baker play an important part in the reliability of the baking test. The method requires special apparatus and materials, and is costly unless large quantities of flour are to be tested. Useful results can be obtained from a little more than half a pound of grain, but the most satisfactory results are generally obtained when larger amounts of flour are available.

While the baking test is the standard test, its many disadvantages have led to numerous attempts to find some simpler substitute for it. A great deal of attention has been bestowed on gluten studies since this constituent has by far the most important bearing on quality. The chemical determination of the gluten (protein) content, calculated from the nitrogen present, has been widely used and, while of definite value, it is not satisfactory as a reliable test of baking quality because it does not assess gluten quality (and also because other factors enter into the problem of strength). Again, it was thought that the percentage of gluten that could be washed out from the flour, or the ratio of wet to dry gluten, might be of service as these vary appreciably, but the results have been disappointing in many cases. Extensive studies of the actual constituents of the gluten, and of the effect of other substances upon it, have proved of limited value, and no perfectly reliable chemical test for discovering the quality of the gluten, or the strength of a sample of grain or flour, has yet been discovered.

Many simple physical tests were also applied, such as moisture absorption, extensibility of the dough, viscosity of flour suspensions, expansion of the dough during fermentation and tests of gassing power, and studies were made of the effect of subsidiary factors such as changes of sugar content and acidity, without discovering any simple test that could be relied on to indicate strength. It is only by combining the information gained from a number of tests that a satisfactory estimate of strength can be made.

The plant breeder wishes to know something of the strength of new cross-breeds as soon as possible, when only a few heads are available. The baking test cannot be used because it requires so much grain, while most laboratory methods take time and are costly. In the absence of a convenient test he has relied on such information as he could get from the appearance of the grain, its hardness when judged by biting it, and the separation of the gluten by chewing. These tests are not reliable, though they do permit of broad distinctions being made.

THE PELSSENKE TEST.

In recent years a new test for both strength and gluten quality has been developed independently in Germany and U.S.A. which appears to be the simple and comparatively reliable test that has been needed; it is generally known as the Pelschenke or Wholemeal Fermentation Test. It differs from practically all previous tests in that wholemeal is used instead of flour, and since wholemeal can be made with an ordinary coffee grinder type of mill, it requires a minimum of special apparatus. It is a rapid test and requires less than half an ounce of grain. The test, as used here, may be described as follows:—

A half ounce of grain is ground in a small coffee mill and passed through a 1 mm. round hole sieve. With a good mill only a little flaky bran is retained by the sieve and this is discarded; if it is re-ground and added to the meal it does not measurably affect the test.

A 5gram sample is weighed into a porcelain dish and 2.7 cc. of a well agitated 10 per cent. suspension of "Nycander" yeast is added from a graduated pipette. The mixture is stirred with a glass rod until most of it adheres to the rod when the dough is taken in the fingers and the last traces picked up from the dish by rubbing it with the dough.

The dough is kneaded in the fingers for approximately 20 seconds, varying according to the nature of the meal, to form a stiff, firm, even dough. If it tends to crack, a little water is added by dipping the finger into water which is then worked into the dough. It is then rolled between the palms to form a smooth ball without creases or cracks and dropped into a beaker containing water at 31° C. Tall 150 cc. beakers half full of good rain water are used. The water in the beakers is maintained at 31° C. by placing them in a suitable water oven or, in hot weather, in a large water bath.

The kneading requires the greatest care and differences in technique at this point may give rise to appreciable variability in the results obtained. It is essential to secure the same dough consistency in every case, and the time of kneading is adjusted accordingly.

Each sample is tested in duplicate and the tests are repeated if the results do not agree well. The duplicate is tested after an interval and is treated independently in every way except for the grinding. The yeast, if stored in a refrigerator in lump form, will retain full activity for several days but only fresh yeast, not more than two days old, is used. If the quantity of yeast suspension is adjusted, samples of less or more than 5 grams may be used and almost identical results obtained. If only a small amount of sample is available, it is better to do two 2.5gm. samples than one 5gm. sample.

The photographs show the behaviour of the dough balls. At first they sink, but after approximately 15 minutes they rise to the top of the water, due to the expansion caused by the carbon dioxide formed by the yeast. After a further interval ranging from a few minutes to several hours the balls begin to break up and fall to the bottom. This generally happens quite suddenly so that two balls of the same dough, after floating for perhaps a couple of hours, may fall apart within a few minutes of each other. The time from the mixing of the dough to the final disintegration of the balls, measured in minutes, is called the test number in the following tables which give the values obtained for a number of representative varieties taken, in most cases, from the crops of the last two seasons. The great variation in time shown by different varieties, and the tendency to uniformity in the same variety grown in different seasons and under different conditions, is rather striking.

NOTES ON TABLE I.

Samples.—The test numbers given in this table were obtained from grain grown on the College Farm or in the Experimental Plots, and they may be considered as typical for these varieties under local conditions. The results have been proved to differ

amongst strains of the same variety. The extent to which they are influenced according to district, or by conditions under which the sample was grown is not yet known, but is thought to be considerable in some cases at least. With a view to examining these effects approximately 250 samples have been collected from most of the wheat growing areas of the State (through the courtesy of officers of the department and numerous farmers) and these will be tested in the near future.

Short Row v. Long Row and Commercial Crop.—In short rows the seed is planted 4in. apart with 16in. between rows, while in the long rows the seeds are 1in. apart with 5ft. between rows. Samples of grain of any variety from either long rows or commercial crops give similar test figures, but these differ materially from the result obtained from samples collected from short rows; the latter are generally from 20 to 30 per cent. higher, the difference being due, probably, to increased nitrogen assimilation and faster finish. Examples of this are seen in the 1933 tests of Dundee, Minfos, and Rancee.

Ford.—The sample testing 81 is a special strain selected here. It shows variations in type as well as quality.

Sword.—The higher figures obtained for the 1933 crop are probably due to a difference in strain.

Fig. 1.—Showing behaviour of wholemeal balls when first placed in the water and after an interval of 15 minutes.

Florence.—Tests between 110 and 40 have been obtained from this variety. It appears to be particularly subject to variation.

Seasonal Variation.—From an examination of the results at present available for the same variety in different seasons, it appears that some varieties are more susceptible than others to seasonal, and probably environmental, conditions.

ESTIMATION OF PROTEIN QUALITY.

A figure which represents the quality of the gluten, which Pelshenke called Specific Protein Quality, may be obtained from the test number by dividing it by the percentage of protein found by chemical analysis. This procedure is based on the argument that the value of the gluten, or its strength as shown by the test number varies independently with both its quantity and quality, that is—

$$\text{Strength} = \text{Quantity} \times \text{Quality},$$

$$\text{and therefore, } \frac{\text{Strength (test number)}}{\text{Quantity (protein content)}} = \text{Quality}.$$

The strength (test number), protein content, and consequent quality of gluten for a few varieties are given in Table II.:—

COMPARISON WITH OTHER PUBLISHED RESULTS.

To illustrate the results obtained by other workers on Continental and American varieties of wheat, and to provide a basis for comparison, the following data have been abstracted from the original papers (1), (2). In all cases where two results are quoted for any class of wheat, they are the highest and lowest given by the authors. Further results obtained from Australian wheats—many from the same varieties as tested here—may be found in the January, 1934, issue of *The Agricultural Gazette of New South Wales*.

MINOR FACTORS AFFECTING THE TEST.

The test may be influenced to a very important extent by the yeast employed. Even when using one carefully selected product occasional variations arise from causes beyond control, and it is therefore desirable to use a standard variety as a check in every batch of samples tested. Because of variations in the yeasts used the test times recorded by different operators are not always comparable.

Fig. 2.—Showing the breaking of balls of a soft or weak variety. The balls have retained a spherical shape.

It has been found that storage of a sample meal generally results in an appreciable increase in the test number; for example, a sample of Ford which tested 60 when freshly ground, gave a test of more than 100 after being stored for a month. The extent of the increase appears to vary amongst varieties; it appears to parallel the increase in strength that occurs in flour during storage, and is probably a matter of oxidation.

Samples of grain examined immediately after they are harvested give unreliable and generally high tests compared with the results obtained from the same samples a few weeks later.

Strong varieties when under test spread out in the beaker as shown in the photograph, and appear to derive some support from contact with it. They do not give quite such a high test in the larger beaker, but it is thought to be more reliable.

DISCUSSION.

Objection must always be taken to any attempt to measure the total of such a complexity as quality or strength by means of a single test. It is not reasonable to suppose that the sum of the behaviour of the numerous constituents in flour, which are subjected in dough making to the activities of a living organism, the yeast, and to reaction with the products of such activities, may be completely assessed in such a simple way. Under certain circumstances, however, such as those imposed by the limited amount of material available in breeding work, only simple, economical tests can be used. It is therefore necessary in such work to select the best of the available tests, and also to discover as much as possible of their special applications and limitations.

In making an *a priori* selection between possible tests greatest importance is naturally attached to either (a) those which isolate and measure a factor of outstanding importance in the main process (as does, for example, the determination of the nitrogen or the gluten content) or (b) those which approximate most

Fig. 3.—Showing how the wholemeal from strong varieties spreads out to form a disc. In the first vessel the "ball" is just breaking.

closely in the conditions they impose on the material to the actual process for which it is required (as does the baking test). Viewed in this way the Pelshenke test does approximate loosely to the earlier fermentation stage in dough making, but it is subject to the influence of offals and germ which are carefully excluded from flour, and to an excessive amount of yeast; it is not subject to the influences arising from ordinary milling and storage of flour, added constituents as salt and improvers, handling and panning, the stress of a full fermentation or baking. Nevertheless, from the results obtained, and as an inspection of the figures given in Table I. will show, this test does distinguish the varieties which are regarded as stronger, such as Cadia, Carrabin, Comeback, Dundee, Ford, Hard Federation, Merredin, and Minister for example, from varieties which are definitely weak, with reasonable certainty. In rare cases, as exemplified by Zealand Blue, the result is at variance with previous opinion of the strength of the variety.

An effort has been made to define the limitations of the test, partly to enlarge knowledge of it, and partly because it seems probable that further study of the why and wherefore of a test which, on logical grounds, seemed inadequate and

which yet appeared to perform so well, might throw new light on the general problem of strength. The attempt is being made to study the main factors of the test independently, namely:—(a) Gas Production which, if deficient, should tend to result in high test figures; (b) Gas Retention which, if deficient, should also lead to high tests; and (c) Extensibility, or the power of gluten to hold the gas formed.

VALUE OF THE TEST.

In view of the data presented in this paper, the test is of undoubted value in cereal breeding. It is probable that it has a definite value to the miller, also, enabling him to select high or low quality samples for special purposes. Since, however, the bulk of the f.a.q. wheat appears to vary over a rather limited range it is probable that it will not give much guidance in the handling or blending of the ordinary mixed commercial samples. It will be necessary to learn what a given range in test number means in terms of improved commercial results before an opinion can be formed of its value for this purpose.

For plant breeding purposes it is also necessary to determine what minimum test should be required of new varieties. From the evidence so far available it appears that a standard test time requirement of 35 minutes might be set, tentatively, with safety. This would ensure a small but definite improvement in quality over our present weakest commercial varieties without leading to excessive culling of varieties which might actually prove valuable.

It often appears to be assumed that the test number bears a direct relationship to strength. Experience indicates, however, that the relationship is not direct, but functional in such a way that a small difference in test number at the lower end of the scale means much more in terms of real strength than a comparatively large difference at the upper end of the scale. There are many evidences of this in behaviour during test, but it is perhaps best illustrated by the results obtained from blending. Though contrary opinion has been heard, we have definitely found that blends do not give the results that would be expected or calculated from a knowledge of the components. Several experiments of this kind have been done here, and the results from one of them are given in Table VI. All of the data given were obtained from one series of grindings, and the individual tests are comparable with those for the blends in every way; for individual varieties they are slightly lower than those given in Table I., but they do not differ by more than is normal for the same sample tested at different times. The duplicate results obtained for the blends are given.

TABLE VI.—*Test Numbers of 50 Per Cent. Blends.*

Varieties in Blend with Test Number.	Av. Test No. of Components.	Test No. of 50 : 50 Blend. (Duplicates.)	Average.
Hard Federation (119) + Carrabin (121) ..	120	120, 122	121
Hard Federation (119) + Canberra (39) ..	79	56, 57	51
Hard Federation (119) + Waratah (30) ..	74.5	48, 48	
Hard Federation (119) + King's White (33) ..	76	48, 49	
Carrabin (121) + Canberra (39) ..	80	56, 57	
Carrabin (121) + Waratah (30) ..	75.5	49, 49	35
Carrabin (121) + King's White (33) ..	77	51, 51	
Canberra (39) + Waratah (30) ..	34.5	39, 39	
Canberra (39) + King's White (33) ..	36	34, 34	
Waratah (30) + King's White (33) ..	31.5	31, 30	

It will be seen that the test figure obtained by blending varieties of nearly the same strength approximates closely to the average of the test of the individuals. A blend of varieties of different strengths gives a test figure below the average of the components. That is, low testing varieties reduce the test of the blend to a much greater degree than high testing ones can raise it. In other words, this particular experiment indicates that the range 35 to 50 means approximately the same in terms of strength as the range from 50 to 120.

It therefore appears that a variety testing between 20 and 30 is much weaker than one testing between 35 and 40, so that by setting a standard of 35 for all new varieties a definite improvement should be obtained. If the exact relationship between test number and strength could be accurately defined it would be of great service, for test numbers alone are likely to give the impression that our wheats are much weaker than they really are. Even at the present time their reputation for low strength does them less than justice.

The test has already proved of value in isolating from several commercial varieties strains that are higher testing and presumably stronger than the average of the variety, though it has still to be demonstrated whether the improvement is transmitted to future generations. From work done here, which will be reported shortly, it appears probable that improved lines can be fixed in this way from some of our present varieties and, if these selections retain the field characters of the variety, the method appears to offer a most economical and rapid way of improving their strength. Similarly, the test offers a convenient check against any falling off in quality in pedigree seed.

CONCLUSION.

Though it is generally agreed that some improvement in the strength of our wheat is desirable, and indeed necessary, if we are to retain and extend our overseas markets it is, as yet, problematical how far we must go. The classifications of wheats based on wholemeal fermentation tests that have appeared in the literature do not give much assistance towards establishing a useful classification for Australian wheat. The strength wanted in any particular market, and the conception of strength in any locality, are largely a matter of local demand and experience, and wheats that would rank as comparatively strong in Europe may be regarded as weak in America.

For example, an eminent Continental authority has stated that wheats having a test number of more than 90 minutes should be regarded as "medicine wheats" to be used to improve the strength of weak ones; that wheats testing between 30 and 90 will make bread without any admixture of stronger wheats; but that those testing below 30 minutes will only make bread with the addition of "medicine wheats." Again, Pelshenke has grouped the strains obtained from his crosses into the following three classes:—(a) High gluten quality wheats having a test number above 60 minutes; (b) fairly high gluten quality wheats testing between 30 and 60 minutes; and (c) wheats testing below 30 minutes and requiring the addition of the (a) group to give flour of good baking quality.

On the other hand, Cutler and Worzella in America classify as weak bread wheats all those testing between 150 and 225 minutes, and their strong bread wheats give a test of from 300 to 400 minutes. Again, very frequent criticism of the quality of English home-grown wheat is noticed in the literature; these, according to Pelshenke's data (Table X. in original paper), probably test on the average between 35 and 40 minutes, and though some popular varieties test much lower, some test considerably higher. But even the best home-grown samples are considered to be too weak to use without the addition of strong, imported wheat.

It therefore is difficult to determine just what degree of strength would give general satisfaction and, in fact, this probably varies considerably in different markets and even in different periods of the year according to the strength of other samples on the market at the time. Instead of trying to follow such changes it seems to the writer that it is desirable to consider how far we can make our wheats complete in themselves. With a minimum of conscious effort on our part, our wheats acquired the character of excellent filling or blending wheats. Jago, in 1911, described them as "choice colour wheats, valuable with reds as mixing," and their strength as "fair," and they have held this trade reputation until recently. Being neutral, neither strong nor weak in any special degree, their strength became a secondary consideration; this seems to be the reason behind the mistaken

idea that they were very weak. Kent-Jones (1927) stated: "There is but little doubt that either the Australian wheats have increased appreciably in strength of recent years, or that the idea that they were particularly weak was a mistaken one Where a good length patent flour is wanted, a large proportion of Australian wheat in the mixture is exceedingly useful."

To pursue this aspect would prolong this paper unduly, but our wheats have been, and all our natural conditions and advantages suggest that they should be, filling or blending wheats; as such, they should not interfere appreciably with the strength of an otherwise satisfactory blend, even when added in large amount. This means, in fact, that they should be capable of "standing on their own" and make a reasonably good loaf without any admixture of other wheat. And they can do this. Though the flour milled and baked locally is, to some extent at least, obtained from selected wheat, no one can deny that really good bread is being made by our bakers every day from purely Australian wheat. To consolidate this position is our most reasonable objective. In passing, it may be noted that the increasing proportion of our wheat milled locally, and the greater tendency shown by millers to select their wheat, must tend to reduce quality in exported f.a.q. wheat which, if these most desirable developments continue, will ultimately become nothing more than the locally unwanted residue.

Assuming the validity of the wholemeal fermentation test results for the comparison—a problem apart from its use in breeding work—the data presented here indicate that some fall in the quality of our f.a.q. wheat has occurred, chiefly as a result of the introduction of a comparatively few of the popular new varieties which have displaced somewhat better ones. A review of all the data available further suggests that the change cannot have been very great. For the present, therefore, it seems certain that we could at least regain our earlier standard by judicious use of present established varieties, and there does not appear to be any need to attach special importance to the really strong varieties that do not yield well as a rule.

In conclusion, the Pelshenke wholemeal fermentation test is regarded as sufficiently reliable to be extremely valuable in plant breeding work, but it would be a mistake to base selection entirely on this test. It must be supplemented by others as more material becomes available, and a baking test must be the final and critical one. It is unfortunate that this test, also, is not without its critics nor its variations and modifications. In the procedure developed mainly in America, and usually followed fairly closely by cereal chemists, the emphasis is placed on what might be distinguished as "blending strength" or ability to compensate for lack of strength in its complement of the blend. For strong wheats the result of this form of the test corresponds well with the result obtained by the commercial baker on the same sample, but when it is applied to wheats similar to ours the resulting loaf is much inferior to that produced by a good baker from the same flour. Consequently, unless a special procedure is developed, which takes into consideration the actual requirements and methods of the trade for which the flour is produced, this test does not assess the *baking value* of the sample. It is, in fact, essential for us to distinguish between strength and baking value and, since we are unlikely to find it profitable to produce really strong wheat, we should concentrate on the improvement and standardisation of its baking value, and the development of tests suitable for this objective. At the present time, in this State, we have no accurate information as to the baking value of any variety of wheat.

EXPERIMENTAL FEEDING TESTS CONDUCTED AT PARAFIELD POULTRY STATION.

[By C. F. ANDERSON, Poultry Expert.]

A series of feeding tests are being conducted at Parafield Poultry Station with a view to ascertaining if suitable foods which are obtainable on the majority of our farms can be satisfactorily fed to poultry. The tests are each of 50 White Leghorn pullets, and commenced on April 1st, 1933.

The feeding is as follows:—

No. 1 Test.—Morning—Wet mash composed of 1 part crushed barley, 2 parts wholemeal (by weight), $\frac{1}{2}$ lb. meat meal, 50 per cent. chaffed greenfeed.

Midday—1oz. wheat per bird.

Night—1oz. wheat per bird.

No. 2 Test.—Dry mash composed of same proportions as No. 1 Test.

Midday—Greenfeed.

Evening—Wheat.

No. 3 Test.—Morning—Wet mash composed of 1 part bran, 2 parts pollard (by weight), $\frac{1}{2}$ lb. meat meal, 50 per cent. chaffed greenfeed.

Midday—1oz. wheat per bird.

Night—1oz. wheat per bird.

No. 4 Test.—Morning—Wet mash composed of 1 part bran, 2 parts wholemeal (by weight), $\frac{1}{2}$ lb. meat meal, 50 per cent. chaffed greenfeed.

Midday—1oz. wheat per bird.

Night—1oz. wheat per bird.

No. 5 Test.—Morning—1 $\frac{1}{2}$ ozs. wheat per bird.

Evening—1 $\frac{1}{2}$ ozs. wheat per bird.

Greenfeed in season.

The following are the numbers of eggs laid by each pen from April 1st, 1933, to May 31st, 1934.

Definite conclusions, however, cannot be given at this juncture with regard to the various methods of feeding. It is necessary for the tests to complete the 24 months before any satisfactory opinions can be formed.

	No. Eggs Laid April 1st, 1933, to March 31st, 1934.	No. Eggs Laid Month of April, 1934.	Total Eggs Laid April 1st, 1933, to April 30th, 1934.

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on May 30th, 1934, there being present Messrs. H. N. Wicks (Acting Chairman), A. M. Dawkins, J. B. Murdoch, F. Coleman, G. Jeffrey, J. W. Sandford, P. J. Baily, A. L. McEwin, A. J. A. Koch, Professor A. J. Perkins, Dr. A. E. V. Richardson, and H. C. Pritchard (Secretary). Apologies were received from Messrs. A. J. Cooke and R. H. Martin.

Leave of Absence.—The Secretary was instructed to apply for six months' leave of absence on behalf of Mr. R. H. Martin, who has left on a business trip to England.

Life Member.—In recognition of 20 years' association with the Agricultural Bureau, Life Membership was conferred on Mr. A. G. Ifould, of the Port Elliot Branch.

New Branch.—Conditional approval was given to the formation of the Wilmington Women's Branch.

New Members.—The following names were added to the rolls of existing Branches:—Yaduarie—Paul G. Fiedler; Wepowie Women's—Mrs. E. Knauerhase; Warrambo Women's—Mrs. J. S. Mitchell; Wandearah—E. T. Sinclair, L. Crouch; Wallala—J. Kinnane; Truro—V. E. Munchenberg; Snowtown Women's—Mesdames T. Fryar, A. Hocking, A. Dolling; Rosedale—B. E. Schwartz, L. C. Schwartz, A. Heinjus, C. Mattiske; Petina—J. Irvin; Mount Gambier—A. E. Clayfield, A. C. Macmillan; Laura Bay Women's—Mrs. E. C. Lowe, Miss A. E. Searle, Miss E. D. Edson; Laura Bay—J. D. Blumson; Jervois—W. Shanklin; Hope Forest Women's—Mesdames W. R. Wheeler, C. Nicol, C. Jackson, H. Justin, P. Wollaston; Gladstone Women's—Mesdames Cox, Jeffries; Coonawarra Women's—Miss Gladys Teichelman; Boors Plains—J. Edwards.

Present number of members, 7,843; present number of Branches, 337.

Several items were discussed in Committee.

GOLDSBROUGH, MORT & COMPANY LTD.,

Head Office: MELBOURNE.

DAIRY AND FARM PRODUCE MARKETS.

MESSRS. A. W. SANDFORD & Co., LIMITED, reported on June 1st, 1934:—

BUTTER.—The production of dairy produce during May was very disappointing indeed. This was, of course, due to the record dry weather conditions experienced, and even although dairymen generally were compelled to handfeed the stock this did not make up in milk returns, for there is nothing equal to the natural pastures. In many districts the fresh cows are coming into milk production, but the backwardness of the season is causing grave anxiety at the time of this report. Sales of butter were well maintained throughout the month, not only locally but the Broken Hill market was largely supplied from Adelaide. The "All Australia Plan" which has been adopted by the Eastern States was not acceptable to South Australia, and for the time being a local stabilisation plan has been arranged, and it is so far working satisfactorily. Prices at time of report were as follows:—Choicest creamery fresh butter in bulk, 1s. 3½d. per lb.; prints and delivery extra. (These prices are subject to stabilisation levies.) Store and collectors' lots, 6½d. to 7½d. per lb. at store door, according to quality. There was only limited exporting done during May, and this consisted more of lower grades than choicest, all the latter being required for local trade.

EGGS.—Supplies during the month under review kept well up, and are now increasing. Values fairly well maintained, but with the approaching of the export season they will have to ease to get back to London parity:—Ordinary country eggs, hen or duck, 11d. per doz.; selected fresh eggs, 1½ozs. and over, 1s. 1d. to 1s. 2d. per dozen.

CHEESE.—Western Australian and local buyers kept the markets cleared from week to week, although consignments received from the South-Eastern factories were heavy. Both for new and matured cheese the trade was satisfactory. Values continued on an even keel, and at date of report were:—Large and medium, 7½d. to 8½d. per lb.; loaf, 8½d. to 8½d. per lb.; semi-matured and matured, 8½d. to 9½d. per lb.

BACON.—The turnover in all cuts of bacon was well maintained, and the usual winter demand was experienced throughout. Hams, however, continued slow of sale, although prices were reduced, but these will be required later on when warmer weather is experienced:—Best quality sides, 9½d. to 9½d. per lb.; middles, 10½d. to 11d.; rolls, 8d. to 8½d.; hams, 11d. to 11½d.; cooked, 1s. 2d. to 1s. 2½d. per lb.; lard prints, 6½d. per lb.

ALMONDS.—The quantities of almonds received in the open markets showed improvement, although the crop this season is not nearly so great as in other years. However, buyers purchased all consignments offering from week to week both in shell lines and kernels, and rates showed an improvement during the month:—Softshells and Brandis, 8½d. to 9d. per lb.; hardshells, 5½d. per lb.; kernels, 1s. 11d. to 2s. per lb.

HONEY.—With the absence of really wet wintry conditions the sale of honey was not nearly so brisk as was hoped. Some shipments were made to both Melbourne and Sydney, but even with these the turnover was insufficient to clear stocks, and quantities are still held in hand by wholesale distributors. Rates, however, have been fairly well maintained:—Prime quality clear extracted in liquid condition, 3½d. to 4d. per lb.; lower grades, 2d. to 2½d. per lb.

BEEWAX.—Supplies were light, and there was no alteration in rates:—1s. 4d. to 1s. 4½d. per lb., according to quality.

LIVE POULTRY.—Sales are held every Tuesday, Thursday, and Friday, and our sale-rooms are the best equipped in the State. The numbers of birds marketed each week in the salerooms was larger than usual, but owing to poulterers and retail distributors having reduced stocks of dressed poultry in cold stores, the demand at each of the livestock sales was well sustained throughout. Fluctuations in prices occurred, more especially with turkeys. It is anticipated that the good demand will continue, and we advise consigning. Crates loaned on application:—Prime roosters, 3s. to 4s.; nice-conditioned cockerels, 2s. 4d. to 2s. 10d.; fair-conditioned cockerels, 1s. 9d. to 2s. 3d.; chickens lower; heavyweight hens, 2s. to 2s. 10d.; medium hens, 1s. 7d. to 1s. 11d.; light hens, 1s. 3d. to 1s. 6d.; couple of pens of weedy sorts, lower; prime young Muscovy drakes, 3s. to 3s. 11d.; young Muscovy ducks, 2s. to 2s. 9d.; ordinary ducks, 1s. 6d. to 2s.; ducklings, lower; geese, 2s. to 3s.; special, to 6s. 9d.; goslings lower; turkeys, good to prime condition, 7d. to 10d. per lb. live weight; turkeys, fair condition, 6d. to 6½d. per lb. live weight; turkeys, poor and crooked breasted, lower; pigeons; 3½d. to 4½d. each.

POTATOES.—New season's, 7s. 6d. per cwt.

ONIONS.—Brown 'Spanish, 5s. 6d. per cwt.

RAINFALL TABLE.

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall at the subjoined stations for the month of May, 1934, also the average precipitation for May, and the average annual rainfall.

Station.	For May 1934.	Av'ge. for May	Av'ge. Annual Rain-fall.	Station.	For May 1934.	Av'ge. for May	Av'ge. Annual Rain-fall.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[The new Bureau subscription rate of 2s. per annum, which was recommended at the 1933 Congress, applies to all members as from August 1st, 1934, with the following exceptions:—Life Members, Branch Secretaries, and members who reside in the same house as (a) a Life Member, or (b) a Branch Secretary, or (c) a subscribing member. Subject to the foregoing exceptions, new members joining during the months of July to December will pay 2s. per annum, and those joining during the months of January to June 1s. for that period and 2s. for each succeeding year. Subscriptions must accompany the nomination forms unless the nominee is exempt.]

MEN'S BRANCHES.

VETERINARY FIRST AID CABINET.

[In view of the outstanding success which has attended the establishment of a Veterinary First Aid Cabinet by the Mundalla Branch of the Agricultural Bureau and because of the wider interest being taken in all forms of livestock husbandry, the following information—supplied by the Secretary of the Mundalla Branch, Mr. A. Ross—is published, in the thought that it may be of value to other Branches of the Agricultural Bureau.]

For some years I had a small veterinary first-aid outfit for my own use, and used to help neighbours with sick animals occasionally.

These people saw the advantage of having an outfit on hand in causes of sickness and accident to farm stock, and introduced the matter at a Bureau meeting. At that meeting a scheme was drawn up giving an idea of what an outfit would need to consist of and an estimate of what it would cost. This was done, and it was left in my hands to go ahead.

GRUBBING

IS A ONE MAN JOB

FOR STUMPS LARGE OR SMALL, GREEN OR DRY,
SHORT OR HEAD-HIGH. THE ENORMOUS POWER OF A
MONKEY GRUBBER

EASILY ACCOMPLISHES THE TASK

Removing the most stubborn obstacles cleanly, with most roots intact.
Easy to handle, simple to operate, expeditious—its only need, regular oiling.
The Standard equipment will clean up everything over 1½ acres from one anchorage.

Each part designed for simplicity, easy handling, and long trouble-free service.

A TIME SAVER AND PROFIT MAKER

ADELAIDE STOCKISTS—Australasian Implement Co., Colton, Palmer & Preston, Harris Scarfe Ltd.,
McPhersons Pty. Ltd., South Australian Farmers' Union.

TREWHELLA BROS. PTY. LTD., TRENTHAM, VIC.

The matter of raising funds did not present any very great difficulties, as the members wanted the outfit and knew about what it would cost to establish it, so donations came in fairly freely, some donating cash and others equipment, such as milk fever outfits, &c. The local Gun Club headed the list with a donation of £7.

While engaged in the preparation of the outfit the idea came to me that it would be a good plan to stage the outfit at our Bureau Social and have it declared open for service by an officer of the Advisory Board. This would give all an opportunity to see and inspect it, and also create an interest that would make it easy to raise more money if necessary.

For this purpose a good cabinet was required. I donated the timber as my share towards the outfit and Mr. Herring (a local carpenter) built it free of charge. Medicines and appliances were purchased with the money donated. After that it was no trouble to get funds—everybody wanted to give something towards it, and it is now as complete as it could possibly be. In fact, it has grown from a Veterinary First-aid outfit to a Veterinary Service, and is just about a full-time job attending to it.

In regard to running the outfit: It is run on business lines on a cash basis. We have a docket book similar to those used by stores, and every purchaser of medicines, &c., receives a docket, a copy of which is filed. By this means we can always check up at any time and see exactly how we stand. A diary is also kept in which every case is entered up with the result of the treatment. This is very important. Instruments, such as milk fever outfits, syringe, &c., are hired out at a charge which it is considered will provide sufficient to replace them when worn out. This money is "ear-marked" for that purpose and is not used for anything else.

The medicines are sold out at cost price, plus about 1d. in the shilling to provide for any bad debts. As the goods are sold out they are replaced, and the thing now keeps itself going. Donations are coming in and will continue to do so from grateful persons who have had animals successfully treated and more equipment is thereby added to the cabinet.

In regard to medicines, drugs, &c.: The local storekeeper, who is a good member of our Branch and very much interested in our work, is supplying us with goods at wholesale prices and our local chemist is also supplying drugs, &c., so that members not only have a first class Veterinary outfit available to them, but are also able to treat their sick animals with the least possible expense. Our doctor, too, is very interested and has offered his help at any time.

Officers of the Stock and Brands office are always glad to assist us at all times. We have found out from experience what is a suitable quantity of each medicine to keep in stock, and a list of medicines, &c., is set out hereunder, with the quantities, which may prove useful to any one stocking up a cabinet for the first time. All drugs, &c., for hypodermic injection, local anaesthetic, &c., the local chemist prepares for me as required:—

Soda bi-carb., 2lbs.
Soda—carb., 1 lb.
Oil—raw linseed, $\frac{1}{2}$ gall.
Oil of turps, 1 pint
Oil—camphorated, 1lb.
Oil—olive, 1 pint
Oil—castor, 1lb.
Oil—eucalyptus, 4ozs.
Copper sulph., 1lb.
Stockholm tar, 1lb.
Methylated spirit, 1 pint
Treacle, 2lbs.
Ginger—ground, 1lb.
Mag. sulphate, 6lbs.
Boric acid, 1lb.
Lysol, 1lb.
Iodine tr., 1lb.
Perm. potash, 2ozs.
Saltpetre, $\frac{1}{2}$ lb.
Petroleum jelly, 1lb.

Zinc. sulph. tabs., 100
Perchloride mercury tabs., 100
Nux vomica, 1lb.
Aconite, 2ozs.
Sweet spirits nitre, $\frac{1}{2}$ lb.
Aromatic sp. ammonia, $\frac{1}{2}$ lb.
Laudanum, 4ozs.
Chlorodyne (vet.), 3ozs.
Chloral hydrate, 4ozs.
Aloe balls, 6
Hyposulphite soda, 1lb.
Iodoform, 4ozs.
Bismuth subnitrate, 4ozs.
Glycerine, 1lb.
Paraffin oil, 2 pints
1 in 8 red iodide blister, 2ozs.
Sulphur, 1lb.
Alum, 4ozs.
Zinc oxide, $\frac{1}{2}$ lb.

A few instruments, &c., that would be absolutely necessary:—

1 or 2 milk fever outfits
1 enema syringe (hose and funnel is good substitute)
1 dressing forcep
1 curved scissors, 7in.
1 measure glass, 2ozs.
1 trocar and canula
 $\frac{1}{2}$ doz. assorted needles
Hank ligature silk
Cotton wool

A piece of 1in. garden hose about 8in. or 9in. long slipped over the neck of a beer bottle is excellent for drenching with—better than an expensive drenching bit.

The medicines and appliances, &c., mentioned are by no means a complete list, but are ample to provide a first-class First-Aid outfit.

We have found out from experience and observation what prescriptions give best results in many cases, and if any Branch is interested the information is available on application.

SOUTH-EASTERN DISTRICT.

MOUNT GAMBIER (Average annual rainfall, 30.55in.).

May 11th.—Attendance, 17 visitors.

CERTIFICATES PRESENTED.—On behalf of the donor of the cup for the best crop of wheat (Mr. A. Patzel), Mr. A. Sassanowsky handed the trophy to Mr. F. L. Koop, who won first with 94 points. A cash prize of £1 ls. also went with the cup. Other prizes were presented to the following:—Class 2 (barley)—Mr. A. H. A. Allen, 1st, with 106.5 points; Mr. L. T. Whitehead, second. Class 3 (potatoes)—First, Mr. B. Kannenberg; second, Clover Estates. Class 4 (pastures)—Mr. W. F. Button first, with 94 points; Mr. Cain, second. Class 5 (oats)—Hill Bros. 102 $\frac{1}{2}$ points, first; second, Mr. W. Harfull, 101 points. Class 6—Snowflakes—No competition. Class 7 (maize)—E. A. Kannenberg, 81 $\frac{1}{2}$ points, first; second, S. Norman, 81 points.

HERD TESTING.—Mr. Sassanowsky thought that the time had come when herd testing was necessary in this district. There was no doubt that the South-East was gradually turning to dairying. The potato industry was practically exterminated, and they had

to take on something where the carriage on produce was not so high. He thought that soon a huge herd testing society in the whole district would be formed, and in the course of eight or nine years the benefit would be apparent. In any part of Europe or America, he said, certain districts had a certain class of cow, and they brought it to the highest point of breeding. They should have that in the South-East. It would be advisable to specialise in the milking Shorthorn or the Holstein, the two outstanding cows for cheese making. (Secretary, G. Gurry.)

APPILA (Average annual rainfall, 14.66in.).

May 4th.—Attendance, 14.

HOME GARDENING.—Paper read by Mr. A. Harvie:—"In laying out a home garden, allow plenty of space when fencing so that when the trees grow up the stock will not be able to reach them. Apart from the pleasure and satisfaction of having a plentiful supply of fresh fruit and vegetables for preparing the meals, most housewives realise the financial saving derived from the home garden. For fruit trees, early and late varieties of apples, apricots, peaches, pears, &c., are recommended. *Vegetables*.—Good cultivation and early sowing are essential for success. It is not always advisable to wait for general rains before sowing seeds or setting out seedlings. The best time to start sowing for spring use is in March, and for summer and autumn use in September and October, but the latter does not apply so much in this district unless there is an ample supply of good water, because it takes a considerable amount of water to keep the soil moist during summer. Turnips, carrots, beetroot, etc., do best when planted in rows and then thinned out. It is not advisable to use stable manure when sowing root crops, but plant in soil that has been heavily manured the previous year. The highest and best drained position of land should be selected for winter cultivation, and the most important point is to keep the soil loose and free from weeds. Transplanting should be done in the evening or on a dull, damp day, and each plant watered immediately after planting, even if the soil is moist. Almost any kind of vegetable can be planted during September, providing one is able to water them when necessary. Tomatoes are hot weather plants, and many failures are caused by too early planting, when the soil is cold and wet. When late frosts are likely to occur, protection is necessary. Before planting cucumbers, the ground should be prepared by mixing well-rotted stable manure with the earth in a trench which has been dug about 6in. deep. Pumpkins, melons, and marrows, &c., require similar treatment. Before the dry weather sets in it is a good plan to mulch with a good layer of stable manure. Beetroot does well in a light sandy soil. On no account use manure, unless dug deeply into the soil. The roots will most likely be forked. The ground between the rows of all growing crops should be kept in a loose, open condition by surface cultivation. The flower garden, no matter how small, helps to improve the appearance of the home, and provides pleasant recreation for most women. Plants can be secured to suit almost any locality, soil, or position. Hardy shrubs make a good display, and when once established require very little attention. The same applies to a hedge, which, if well clipped, gives a neat, complete appearance to the garden." (Secretary, E. Wurst.)

WARCOWIE (Average annual rainfall, 12.31in.).

May 1st.—Attendance, 13.

FARM ECONOMY.—Mr. L. Jarvis read the following paper:—"Horses are to be found on nearly every farm, and of all farm animals should be kept as few in number as possible. It is a good plan to breed a few foals each year to maintain a team of young and active animals. Harness should be oiled at least twice a year. Mutton fat, neat-foot oil, and a little Stockholm tar make a good harness dressing. Implements are too often left standing in the weather; one season in the open does more harm than the work they do in two years. A good shed of timber and straw will guard them

against all weather. All woodwork of the machinery should have a coat of paint occasionally. Fences should be re-strained if wires become broken or slack, and new posts used to replace any that are broken. This will make the fence last for a number of years. Gates can be constructed at little expense out of old piping or a few shillings' worth of timber and a few bolts. Hinges can be made out of old parts of machinery. Tools should always be kept in the one place; it often takes longer to find the tools than it does to do the job."

Mr. F. Williams read a paper, "Mendelism." (Secretary, A. Crossman.)

THE OAT CROP.—The Hon. Secretary (Mr. E. Pitman) contributed the following paper:—"The farmer who grew oats for sale last year found them a very profitable crop. Throughout all of the older settled areas there has been a very keen demand for seed oats. Oats can be grown with very little trouble if sown early in the season, i.e., by, say, the middle of May. My practice has been to grow oats on wheat stubble ground, sowing direct with the combine on the burn, as soon as possible after burning. Sown on fallow, oats produce a rank, high crop that is difficult to either cut or reap. I have grown Algerian, Mortgage Lifter, Sunrise, Cape, and Guyra, and while giving

satisfactory yields, most of them are not early enough to be done with before the wheat was ready to reap. Mainly for that reason I have grown Early Burt for a number of years. I am trying a small area of Palestine oats this year. Early Burt is a fairly sweet oat; most livestock will, when grazing, leave other crops alone and feed off this variety. If cutting oats for hay, cut according to the time needed for the variety grown. Some oats if cut green prove bitter when chaffed up, while others, if left to ripen, are not eaten very readily. As oaten hay alone when cut for chaff is heating on horses, I prefer, if possible, to put in the stack alternative loads of oaten and wheaten hay which makes good feeding chaff for stock. If leaving the oats to strip and the crop is at all heavy, make a big lip sieve for the header. Oats can be stripped in much cooler weather than wheats. *Storing*.—I much prefer to tip them out loose in a corner of the barn, building a bag wall to keep them up. If stored in bags, rats and mice do a lot of damage." In the discussion which followed all took part. Mr. Borgas said that oats at a clearing sale realized 12s. 2d. a bag, and they were being delivered at Port Augusta for sheep feed from Kimba at 8s. bag. He preferred Pride of York for grain, being a plump, short-strawed variety that did not shake in rough weather. He preferred to cultivate before sowing and found oats cleaned the weeds off a paddock better than any other crop. Oats for hay should be cut fairly green. He would sow one bag of oats to 2 acres, and thought every farmer could use for hay and grain from 30 to 40 acres each year for his horses. Mr. Joppich spoke of the large areas of oats grown in Western Victoria, where the oats were fed off by stock to a large extent. Oaten stubble was one of the best feed stubbles for all livestock. He ploughed a "lay-out" paddock, and although the ground would not work down, he reaped a 7½-bag crop. He preferred to fire-work stubble land before sowing oats. Mr. Bleischke said they were trying out oats this year as sheep feed, and asked how much per acre should be sown. Mr. Pitman advised about two bags to 5 acres. There would probably be some very cheap oats in 1934-1935, for nearly every farmer was sowing this seeding. It was a waste of time and labour to grow oats on fallowed land.

SUTHERLANDS (Average annual rainfall, 10.88in.).

February 8th.—Attendance, 55.

Mr. W. C. Johnston (District Instructor) delivered an address, "Sidelines on the Farm."

A special meeting was held on February 23rd to discuss pasture experimental work. **BOOKKEEPING**.—Mr. W. Twartz read the following paper at the March meeting, which was attended by 14 members and 9 visitors:—"Every farmer should do a certain amount of bookkeeping, the same as other business people. The farm is a business, and it is very necessary to know whether it is a paying proposition. It is too great a tax on the mind to attempt to memorise the many affairs connected with the working of a fair-sized farm. The practice of recording transactions on odd pieces of paper, and reference to the heel of a cheque book or a file of receipts, is very unsatisfactory. To enable a farmer to correctly estimate his profits and losses it is absolutely necessary for him to keep books. Farmers should keep separate books for each sideline, as well as for the farm. The number of books will depend on the nature of the business, but three books are absolutely necessary, viz., waste book, journal, and ledger. The waste book contains a record of all transactions as they occur, but for temporary purposes only. From the waste book the items are entered into the journal and ledger. Every 12 months the farmer should make a valuation of his stock and plant, and draw up a balance-sheet. Double entry bookkeeping has many advantages over single entry, and is so called because each transaction is recorded twice—one relating to the giver, the other to the receiver. Farmers that have really no knowledge of bookkeeping should at least keep records of income and expenditure, and all receipts and account sales should be filed. By doing bookkeeping on the farm farmers save a lot of time and money, especially when filling in income tax returns. Farmers who have sheep should

also have a special book for wool and shearing records, showing how much wool was clipped and how many sheep were shorn. The number of sheep on the holding should be recorded from time to time, and any sold or slaughtered deducted. Farmers should keep a crop record showing how many acres sown, times worked, kind of wheat, &c., and the number of bags reaped. The number of cows milked during the year should be recorded, and when the cream cheque comes the butterfat lbs. booked down, and at the end of the year it will be easy to calculate how much each cow is giving. By keeping these records it is easy to see if the farming methods are improving, and if the farm is carrying more and better stock. It will also facilitate the compilation of statistics. Trusting to memory is a very unreliable way of doing it. Where farmers have a rain gauge the falls should always be recorded, and it is always handy to know how much rain has fallen on the farm for the year. It is just a few minutes every now and again to keep particulars up to date, and the information obtained will be well worth keeping. The principles of bookkeeping are in every way necessary for a farmer's business, and the little time spent will be amply repaid."

STORING FODDER.—Paper read by Mr. L. Niemz:—"During seasons of periodical drought farmers turn their attention to the all-important question of fodder storage. A large number of farmers in this district do not give this important matter due consideration. While seasons are bountiful they forget to reserve fodder for the lean years which will come again. An important operation of farm activities should be the conservation of fodder of some description. Every farmer should make large stacks of straw in good seasons which will last for many years without getting damaged by weather or mice, and in time of drought it can be fed, mixed with a little hay. This would be much cheaper than purchasing hay chaff at a high price. The best method of storing fodder for dairying cows in good years is to make ensilage. Hay conservation does not appear to be the most successful, because of mice. Cocky chaff is also a valuable fodder. When storing hay and chaff each should have a good bedding of straw and good straw covering to prevent damage by rain and mould. If preserved under a good shelter it will keep for years. Ensilage is not suitable for feeding horses." (Secretary, E. Schiller.)

TRURO (Average annual rainfall, 19.95in.).

February 19th.—Attendance, 15.

HARVEST REPORTS.—Trophies for this year's local Crop Competition were presented. Mr. L. Miller gained the first prize with 95 points with Gallipoli and Nugget varieties of wheat. Mr. W. Rice was awarded second prize with 90.5 points with Dan and Sword wheats. The crops through the district averaged from 8 to 30bush. on fallow, the lower returns owing to the early sown ground becoming set due to the early rains. Ploughed ground returned an average of 16bush. Oats averaged 8 to 15 bags and barley 9 to 10 bags. Hay cuts were up to the average, yielding from 30cwt. to 2 tons per acre. (Secretary, L. Davis.)

WASLEYS.

February 8th.—Attendance, 14.

HARVEST REPORTS.—Mr. T. Day reported: Throughout the district Sword proved the best variety. He had not seen a bad crop during the four years it had been grown. Yield, 34bush. Nabawa only yielded 18bush. and was inclined to grow rank. Prior's barley sown on late fallow produced 38bush., and 20bush. were obtained on stubble land. Mr. R. Currie: Sword 28bush. on fallow following oats. Nabawa on fallow after wheat 12bush. Barley on grass land ploughed prior to sowing during May yielded 27bush. as compared with 18bush. on stubble; both treated with 50lbs. of 45 per cent. super per acre. Oats on stubble land and fed off twice yielded 1½ tons of hay as against 1 ton on land ploughed up after grass; both sown with 60lbs. of 45 per cent. super per acre. Mr. A. Sellick: Sword, early sown, 33bush. per acre. Ford frost affected. Nabawa on poorer fallow 18bush. per acre. Barley on stubble land 15bush. good sample; whilst oats on stubble only grew feed, although 2bush. was sown per acre together with 1cwt. super. Mr. E. Day: Sword (Selection No. 1) yielded 9bush. better than Nabawa. Glucub yielded the same as Nabawa. Sword (Selection No. 2) yielded 3bush. more per acre than first variety, very tough to thresh, but grew very thick. Taldra 18bush., against Sword 33bush. Mr. L. George: Sword 33bush, Ford 24bush., Nabawa on ploughed land 15bush. Mr. J. Koch sowed Sword (Nos. 1 and 2), much preferred No. 1 as it stood up better, whilst No. 2 had to be reaped one way during hot weather. Barley sown with super and ammonia on stubble land produced 2bush. more per acre than that sown with super. Better results were obtained on clay land following oat pasture ploughed in February than on stubble land stirred up with cultivator. (Secretary, C. Currie.)

YORKE PENINSULA DISTRICT.**WHEAT DISEASES.**

[Paper read by Mr. L. Carter at the April meeting of the Boors' Plains Branch.]

From time to time wheat yields are considerably lowered by the devastating attacks of various diseases such as stinking smut or bunt, loose or flying smut, flag smut, take-all, foot rot, rust, &c. Each disease is caused by a parasitic fungus which may cause severe losses at some period or other in practically every district. Fortunately rust is somewhat intermittent in its attacks, several seasons often elapsing between serious outbreaks. Frequently others are met with year by year and tend to cause increased losses unless special control method are adopted to combat them. For years efforts have been made to produce resistant varieties and partial success has been achieved in several cases. Early maturing rust escaping varieties have been produced and extensive experiments carried out to combat flag smut, &c., but complete success is difficult as varieties displaying these characteristics have been found in numerous cases to be far from prolific enough.

SMUTS.

The two wheat diseases, bunt, ball smut or stinking smut, and loose or flying smut are commonly known as smut. When a farmer refers to smut he usually means stinking smut or bunt which is caused either by *Tilletia tritici* or *Tilletia laevis*, two closely related fungi. Stinking smut and flying smut differ greatly, but from the growers' point of view the main one is in the treatment of seed. Stinking smut, which gets its name from the objectionable smell noticeable if only a little is present in the grain, can be treated in infected seed, but to do so in the case of flying smut requires a very intricate process.

STINKING SMUT OR BUNT.

In this disease minute black particles are frequently found adhering to the grain and though commonly called smut they might more correctly be defined as bunt as they are really the spores of a fungus just as grains are the seeds of the cereals. Germinating in the soil the fungus growth of these spores under suitable conditions enters the germinating seedling and grows with it, living on the plant tissues to finally produce the "bunted ear." Enclosed in the ovaries and glumes these spores cannot escape. At first they appear somewhat greasy, but later they dry and harden. This mass of spores in the ovary is spoken of as a bunt ball, resulting in the disease being commonly called "ball smut." The fungus grows to maturity with the plant, and finally produces spores in the ear which replace the normal grain. These spores are produced in enormous numbers, one single bunt ball no larger than a wheat grain being calculated to contain approximately 4,000,000 spores, which if evenly distributed are sufficient to supply each grain in a bushel of wheat with from 4 to 6 spores, each capable of causing the resulting plant to be diseased. Infection from soil which has previously grown smutted crops is possible, though fortunately is relatively rare. The chief cause of the smut is the sowing of seed with healthy spores adhering to it. It follows therefore that if the vitality of these spores can be destroyed or the fungoid growth resulting from such spores is destroyed the crop will be clean. Methods have been introduced which successfully bring about such results. Occasionally as in self sown crops there may be sufficient moisture present in the soil to germinate the spores of the fungus without germinating the wheat. As a result the fungus plant is unable to attack the wheat and dies before the wheat germinates. Too much is left to chance by trusting to this hazardous result so that early sowing is not sufficiently trustworthy for farmers and pickling methods are recommended.

COMPARE YOUR COSTS!**CATERPILLAR****DIESEL****"Thirty-Five"
TRACTOR**

In the Clare District cultivated 800 acres in 175 hours

WHEAT PICKLING.

Seed Treatment as a Control Method.—Satisfactory success in combating stinking smut has resulted from treating seed prior to sowing. Two distinct treatments are available, namely dry dusting with copper carbonate and wet pickling with bluestone (copper sulphate) or formalin.

Dry Pickling.—Thoroughly dusting wheat grain with copper carbonate powder at the rate of approximately 2ozs. per bushel has proved comparatively satisfactory control of this disease in seed samples not seriously infected. Furthermore, copper carbonate appears to prevent injury from attacks of ordinary soil fungi, thereby improving the yield in some instances where non-smutted grain has been treated with the powder before sowing. The dry method of pickling has advantages over the wet methods in that it may be done at any time of the year and the grain so treated stored until required for seeding. Further, it is less troublesome and fool-proof to carry out since no solution of correct strength need be made up as is necessary in wet pickling, to overcome the danger of lowering germinating capacity of the seed by using solutions of incorrect strength. It must be remembered that the powder if breathed causes nausea and in large quantities is poisonous so that in dusting, an air-tight churn should be used if possible. The farmer is recommended to always pickle in the open where if a little care is exercised there need be no fear of any ill effects ever resulting.

Wet Methods.—Bluestone pickling has become obsolete in many districts on account of the poor germination often resulting from seed treated with this pickle. Where this wet method is still used the solution recommended is 1-1½lbs. copper sulphate to 10galls. of water in which the seed is dipped for 3 minutes then drained and allowed to dry for at least 12 hours before sowing. Unfortunately reinfection may take place immediately the solution has dried, as this pickle is only effective while wet. In the case of badly bunted wheat samples fresh seed samples should be selected, but if the farmer must sow the dirty seed it is recommended that he first pickle the seed in a bluestone solution (1½lbs. copper sulphate in 10galls. of water) then spread the seed on a floor or tarpaulin and immediately sprinkle the whole with a solution of limewater (1lb. of quicklime to 10galls. of cold water, using the clear water decanted off) and turn the seed several times with a shovel. If formalin is to be used care should be taken that a ¼ per cent. solution be used (1lb. formalin to 40galls. of water). Though formalin if correctly applied does not hinder the germinating capacity of wheat seed as much as bluestone, it has been found that where the seed is not sown within 2 days, a poor germination results. Wherever wet pickling methods are used the farmer should float off as many bunt balls as possible.

LOOSE OR FLYING SMUT.

Wheat affected with this disease which is caused by the parasitic fungus, *Ustilage tritici* frequently has somewhat stunted stalks. The smut is produced in the ovaries and destroys the parts of the flower. The spores produced are a blackish powder easily blown about, which characteristic, together with the freedom from objectionable odours, serves to distinguish this disease from stinking smut. Infection can only be produced by spores which are blown on the flower just after heading and cannot result from spores on the outside of the grain or in the soil. Under favourable conditions the spores germinate, the fungoid threads produced entering the ovary and remain dormant in the embryo of the apparently normal grain. These threads grow up with the plant when such infected grain is sown and produce the disease once more so that the treatment recommended for bunt has no appreciable effect on this disease.

Control Measures.—Seed should always be selected from a crop which examined at flowering time proved to be unaffected. Fortunately the disease is not nearly so commonly met with in South Australia as stinking smut. Where it is necessary to sow seed infected with this disease the hot water method is recommended. There are several modifications of this intricate treatment though both are tedious and far from convenient on the farm. In America they advocate soaking the seed for 10 minutes in hot water at a temperature of 129°F. or 54°C., taking pains to maintain a constant temperature.

FLAG SMUT.

The parasitic fungus *Urocystis tritici* causes the disease known as flag smut, which is sometimes responsible for serious losses in wheat crops, reducing the yield in some cases as much as 50 per cent. In its early stages the disease, which only attacks wheat, is difficult to detect. Later the leaves take on a leaden or faintly bluish hue. As the crop heads it is noticeable that the flag is curled and abnormally grey. At harvest time the grey flag breaks into innumerable fine sooty black spores which are readily distributed over the soil and throughout the harvested grain. The disease may be propagated by the germination of spores in the ground or of spores attached to the seed.

Control Measures.—Though copper carbonate has proved effective in treating spores attached to the seed grain it is apparently not sufficient to combat the spores already

in the soil. Introducing rotations where another crop not susceptible to the disease is sown, followed by a year's fallow before sowing wheat, for example oats-fallow-wheat has proved very effective. The seedbed should be thoroughly prepared early and shallow sowing of early maturing varieties such as Nabawa and Yandilla King, &c., is recommended. Burning the wheat stubble destroys many spores which might otherwise be left healthy and free to attack the next wheat crop sown. The practice of feeding livestock with diseased hay is indeed unwise, as it has been proved that the spores of flag smut pass uninjured through animals.

STEM RUSTS.

These appear later in the season than leaf rust, and may be observed in the commencement of summer. The first signs are pale yellow spots on the leaves evident when the plant is held to the light. Some days later large reddish orange patches develop, around the edges of which may be seen the ruptured epidermis or leaf covering. This rupturing of the epidermis is a feature which characterises stem rust from leaf rust. Numerous spores, known as uredospores or summer spores, are produced on these reddish patches throughout the season. Being small and light they are readily distributed by the wind, and under favourable conditions start new centres of infection in neighbouring plants. In severe attacks the spores are so numerous that the surface of the ground may appear red owing to a covering of these reddish spores. As the summer advances and the plants mature the reddish patches change to black owing to the production of black resting spores or teleutospores. Teleutospores are incapable of infecting wheat but may carry over the disease on the Barberry plant which is fortunately rarely found in Australia. Stem rust reduces the yield, and the grain if present is generally small and shrivelled, whilst the straw is brown or greyish brown and brittle. In severe attacks no grain forms and the brittle straw is useless. The severity of rust attacks depend on many factors, warm weather, frequent showers, and heavy dew favouring the development of rust. Early maturing varieties may ripen so early that the grain is fully formed before infection occurs, in which case little damage may occur. Some fertilizers affect the final degree of rustiness of plants by hastening or delaying the ripening process. A few days difference in the ripening of two fields of wheat may have a marked influence on the amount of rust which develops. Super hastens maturity, aiding the crop to escape rust, while nitrogenous fertilisers predispose the plant to disease by increasing succulence, and lodging and by delaying

maturity. Barley is susceptible to the stem rust of wheat, but oats are not attacked. There are two distinct strains of stem rust and apparently some wheats are susceptible to one strain and resistant or escape the other strain, and *vice versa*, while yet other varieties of wheat are susceptible or *vice versa* to both strains of the disease. The solution therefore appears to be in selecting and breeding rust escaping varieties suitable for the various districts. Liberal applications of superphosphate are recommended.

LEAF RUST.

The damage occasioned by this rust (*Puccinia triticina*), while far less than that caused by stem rust, is often of some importance in our crops, appearing later in the season than stem rust. This disease is almost entirely restricted to the leaves, upon the upper surface of which it causes light yellowish-red scattered rust spots which do not rupture the epidermis, which is a distinguishing factor when comparing stem and leaf rusts. Later in the season black teleutospores are produced, which serve no useful purpose in the life cycle in Australia. The red uredospores are responsible for propagating this rust in Australia and carrying it over from season to season. Fortunately this leaf rust only attacks wheat so that the introduction of suitable rotations assists in starving out the disease.

Control Measures.—Early maturing resistant or escaping varieties of wheat should be sown and liberal quantities of superphosphate drilled with the seed that the plants may have every opportunity of maturing early, so escaping severe leaf rust attacks. Careful fallowing and early seeding are beneficial. In very wet soils drainage may prove to be of assistance as very damp conditions tend to favour the spread of rust.

TAKE-ALL.

The fungus *Ophiobolus graminis* which causes take-all exists in the soil and attacks the roots of the wheat plant. At first the disease makes its appearance in patches which are usually round, being large or small according to the severity of the attack. Sometimes the affected plants give rise to ears which are white and possess no grain, which has led to the term "white heads." Only in rare cases is any grain present in these "white heads" and if found is pinched. The straw of such plants is found to be discoloured at the base or butt and blackened from the ground level upwards for as much as two inches. Roots, especially in the later stages of the disease, show an abnormal development of root hairs producing a "fuzzy" or "woolly" appearance. Further, the roots become brittle and break off readily if pulled up. Sometimes an excessive development of secondary roots is noticeable. In later stages the butts of the plants are frequently completely rotted through and the leaves above show malnutrition. Examined microscopically the plants show a felt-like mycelium of fungoid threads or a plate of brown to black colour is noticed encrusting the stem and leaf sheaths of the plant at the base. These threads ramify the tissues at the base of the plant and cause the early death of many cells. In very advanced stages the blackened basal straws may show the development of fungoid spore cases which shed loose spores into the soil. All infection takes place from the soil, the young growing wheat plant being attacked by the fungus, the threads of which enter the plant near the ground level, establish themselves in the root system and lower portions of the stems living parasitically at the expense of the wheat plant. Other hosts affected and conveying the disease are barley grass, broome grasses, pyrum, &c. Cultivated barley is attacked, but oats only rarely.

Control Measures.—Burning stubble of a take-all crop certainly destroys many spores on the surface but those in the soil are generally unaffected. To defeat these healthy spores the farmer must introduce oats into the crop rotation (if not already practised). Such familiar rotations as early fallow, oats, early fallow, wheat, or early fallow, oats (feed off), oats (harvested), fallow, wheat, assist in killing out the disease. It has been recommended that where severe attacks of the disease have occurred no wheat crop should be sown for at least five years. Under no condition should the farmer plough take-all patches when dry and dusty, as this materially favours the spread of the disease spores. Late fallowing is claimed to be worse in the case of take-all ground than no fallow at all. Many favour the seeding of early maturing varieties which may get a good start on the disease. It should be emphasised that where an attack of take-all is to be feared no wheat crops should be fed off, as the setback to the plants apparently predisposes them to attacks from the disease.

FOOT ROT.

It is considered that the disease foot rot is caused by either of the two parasitic fungi, *Helminthosporium sativum* or *Wojnowicia graminis*. Outbreaks are generally observed shortly after flowering time. Isolated heads appear to be ripening off prematurely, and either fail to set grain or produce grain which finally becomes shrivelled and practically worthless. Though most frequently seen in scattered patches the disease may occur in definite areas. Plants affected are sometimes killed in the seedling stage, whilst in more mature plants poor stooling may result, and only a few heads set seed. As in

take-all, which disease foot rot closely resembles, there is an abnormal development of secondary roots, causing a "fuzzy" appearance. Furthermore, the roots are so brittle that they break off easily if the plant is pulled up. Close examination of such plants at or below ground level shows characteristics brownish markings of the straw and leaf sheaths. Sometimes the markings are in the form of brownish tobacco-coloured streaks or spots, and at other times there is a uniform discoloration of both straw and sheath. In a dead plant the destruction extends into the straw, and the basal colour of the plant is ashen grey, though sometimes it may be charred or black as in take-all. Infection takes place via the soil, consequently stubble and refuse serve as hosts to carry it over from crop to crop. Only in relatively few cases is the disease carried over in the seed, in which case a brownish discoloration is noticeable at the germ end of the grain. Never sow seed showing indication of the presence of foot rot. Barley, barley grass, Brome grasses, and spear grasses are attacked by this disease, but oats is immune.

Control Measures.—Where the following are practised the losses caused from this disease are minimised. All stubble and refuse should be burned. Rotations including bare fallowing and oats as recommended in the control of take-all have proved beneficial. Good plump seed samples should be selected where possible, and early sowing employed in a carefully prepared seedbed. As in the case of take-all the practice of feeding off should be discouraged, as the resulting setback to the plant is dangerous.

PREPARATIONS FOR SEEDING.—Paper read by W. J. Bagnell:—“Seeding is the beginning of the year’s profits and therefore the land should be well cleared of stumps, stones, weeds, and shoots if they can be destroyed. Good fallowing is half the battle. Fallow on heavy land should not be too deep, it spoils the subsoil which is very close to the surface—at least from 3in. down. Scratching instead of fallowing is a useless proposition. The cultivator is a good fallowing implement providing it is used at the right time, but if the ground is too hard or boggy it does not make a satisfactory job. The cultivator does not turn in grass which may lead to diseases. Working back fallow should be crossed as much as possible to cut through all the ground. Working back the fallow is important and should be done at least twice a year. Fallow land is the most profitable, therefore do not overdo it by trying to do more than can be done satisfactorily. The first working after fallowing in September gives the ground a good airing and kills weeds. A second working can be given in February, and a third if necessary before seeding operations. The second should be well done and all weeds killed, because there may not be time to go all over the same ground again before seeding. If shoots on the fallow are too big for the seeding implements, they are best cut, raked, and burnt. Anything to delay seeding operations should be done as soon as possible after harvest. When working back the fallow, it is a mistake to work deeply, it may spoil the firm seed bed, but go as deep as is necessary to root up all weeds that are in the furrows or hollows.” (Secretary, G. Smith.)

WHEAT AND WOOL.—Paper contributed by Mr. E. Peltz (Hon. Secretary):—“When farming in this mallee district a farmer should grow wheat and wool, making both his main line, for wheatgrowing alone in this district is never a paying proposition, even at an average price, and wool on its own is not advisable either, because a farmer would not be able to meet his liabilities, although last year’s wool receipts exceed those for wheat. This light, sandy country does not stand any heavy cropping; it can easily be overcropped, and by extensive cropping it will drift more rapidly, especially when being fallowed. If the land is not fallowed it will not grow a paying crop unless an artificial manure is found that will give the same results off grassland fallow. A great deal of this country—as soon as it is cleared—should never be broken up for fallow or wheatgrowing, chiefly white sandhills. Sown with oats and grasses, top dressed every four years, and then used for grazing only would be the best paying proposition for the white sandhills. This land is too expensive to work against the low-yielding crops that grow on them. It might be difficult sometimes to keep them separate, but they could be top dressed when the better ground is in wheat if in the same paddock. That would give the grass a chance to seed and get a decent covering over the sand. A farmer should try and divide his farm into no less than seven paddocks—in addition to the small feed paddocks—to get one year’s fallow, one wheat, one oats on stubble, and the remaining four for grazing. That would give the ground four years’ spell, and get it into better heart by running sheep on it, after which

it could be fallowed and cropped with wheat, &c. Then one sheep on $1\frac{1}{4}$ acres on the grassland could be run, which will give about two acres to one sheep over the whole farm, providing that the land is free from shoots and sown with various grasses. When it is all well grassed it might carry more, but overstocking is a poor policy; it is better that some feed is wasted rather than make the sheep have to suffer. The latter tells on the lambs and wool prices at once. When that many sheep are carried provision must be made for years of drought. Keep oats and hay on hand for hand-feeding. By working a farm on this rotation there would be no need to have such a strong plant for cultivation, the working expenses would not be so great, and the crop returns per acre would be better. The expenses in keeping a flock of sheep are not so very great. Be careful when selecting ewes which are to be the foundation of the flock—big framed, young Merino ewes are the best to buy. Keep a good type of medium woolled Merino ram, and always select from the same blood if possible. At shearing cull out the inferior ones, and keep young lambs to replace them. If interested in fat lambs keep one or two English rams, and mate them with the ewes that have the best wool. Sell those lambs as soon as they are fit, and never keep them over for next shearing. Keep the Merinos to maintain the flock. It takes many years of hard work and cash to get a new block into the rotation that has been suggested, but the farmer should have a plan drawn out under what system he intends to work his farm, so that it does not interfere with clearing and fencing operations. If this system is carried out a farmer will not go far wrong under normal prices and seasons, and will obtain the best results from his farm in the mallee."

Phalaris tuberosa is well established on Mr. W. T. Vigar's grazing land at Eden Valley.

TICK IN POULTRY.—Paper read by Mr. J. Boehm:—"Almost every fruitgrower keeps a few head of poultry, and as a rule the fowlhouse is built either of iron, bushes, bags, or hessian, and very little care taken of the house or fowls. Finding that my fowls were very badly infested with ticks. I mixed about 2 tablespoons of sheep dip in 8galls. of water, and dipped 6 fowls and left them for two days, then I made another inspection and found the tick almost cleared. So I mixed another dip, this

time using 3 tablespoons and dipped the whole flock. About 10 days later I examined 3 hens and found no more tick on them. We have since killed a number of roosters, but no more ticks have been seen and no more fowls have died. Another cure is to brush oil over the fowls. The best oil to use is the oil drained out of a motor car or any other oil from an engine, but the dip is quicker and is always effective." (Secretary, J. Odgers.)

THE AUSTRALIAN HORSE.—Paper contributed by Mr. C. Faehrmann—"A little over 100 years ago, when the first railway journey in history was made, men said that the age-long friend of man would vanish from the civilization which it had helped to create, but such was not the case. Instead, horses multiplied in spite of the trade and traffic carried on by the railways. Horses were needed by the man on the land to convey his heavy loads to the railway centres. Other trades arose and horses were again called in for their development. When the Great War broke out in 1914,

coal was the vital material needed for munitions, industries, medicines, fuel for the Navy and merchant fleets, which carried men and food from all parts of the globe. This coal could not be produced without the aid of tiny ponies who hauled it along the narrow ways in the mines where machinery could not be safely employed. Without these ponies the ships at sea, and the railways, would have ceased to run. The history of the horse runs back into centuries, and it is generally believed that the horse originated in America, from where it became distributed throughout the whole of the earth, and man by his arts, has developed the horse to suit his requirements. The breeding of horses in Australia was commenced in a small way, between 1,780 and 1,800, and the stock gradually increased until it has reached a total of about 2½ millions. The Australian horse is regarded as being the toughest domesticated horse in the world. Australia is an ideal horse-breeding country, for the climate is so suitable that winter stabling of stock is rarely necessary. At various times, however, severe droughts are experienced in certain parts of Australia. Gradually water

On Mr. D. F. Sheppard's property at Prospect Hill the Advisory Dairy Council recently inspected a good cut of Clover and Grass Hay.

supplies diminish until dams, creeks, and other sources of water became exhausted. At such times the thirsty animals have been known to dig holes several feet deep in the beds of creeks searching for water. In most cases the grass disappears before the water gives out. Though hundreds of animals may die before relief is available, it is surprising how many survive. Bred in many cases from the survivors of the above conditions, the Australian horse inherits a measure of toughness that is not possessed by the horse of any other country. His power for 'picking up' and regaining good condition rapidly, when the first rain comes, is very surprising. During the Great War and also the Boer War, in which horses were used in great numbers, the Australian horse established a record for endurance which has not been equalled by the horses of any other country. In some cases, during the campaign in Palestine, horses were known to go without water for 84 hours, covering in the meantime large distances, with up to 20 stone on their backs. The present generation is doing very little to maintain the splendid breed of horses that have been handed down to them.

The heavy draught horse standard has certainly been improved by careful breeding throughout most of the States of the Commonwealth—particularly in Victoria and parts of the South-East of South Australia. On the other hand, the lighter breeds—hacks, hunters, buggy, and light van horses, probably due to the advent of the motor car—are not quite up to the standard. The breeding of thoroughbreds is fairly well catered for by racing followers, but there is a strong tendency for those breeders to see only two points of view—speed and the winning of races. When attending important racing fixtures it is remarkable to note the number of geldings and the small number of entires. Many of these geldings, when their racing days are over, would make excellent station sires if they were not gelded—with a view of making a racing machine of them. The army is chiefly concerned in the breeding of utility horses suitable for military purposes. Two types of horses are required—a cavalry horse from 15 to 15.3 hands of the hunter stamp, with substance, quality, and true action; and a small, compact, light draught horse, from 15 to 15.2 hands, with short back, deep body, strong quarters, plenty of bone, and a good, true walker, suitable

Mr. G. Cleggett, of Mount Barker Springs, exhibits a very fine stand of Perennial Ryegrass and Subterranean and White Clovers.

for artillery purposes. These animals are becoming harder to obtain. There is a demand for them every year from India, Java, and other countries, approximately 6,000 horses a year being exported, in addition to which about another 5,000 a year are required in Australia. In recent years it has been rather difficult to obtain the standard required by these countries. In some years the Indian Government has had to go short of its requirements because horses of the required type were not available. At other times they have had to take reluctantly a horse which falls below the required standard. Unless greater attention is given to the production of the types required overseas in Australia, we are very liable to lose our valuable overseas markets. Horse breeding could be made one of the agriculturist's most attractive sidelines, but it is being neglected. If the present rate of deterioration in the type of horse being bred is allowed to continue it will only be a matter of a few years before Australia will not be able to command a market for her horses. There is an inclination among some breeders to believe that the motor has done away with the demand for the horse. It is admitted that many horses have been replaced by mechanical appliances, but there are still many activities in which the horse is indispensable, and for which he

will be in demand for many years to come. Especially is this the case with army remounts in all countries. Even with the reduced cost of motor fuel, the horse is gradually 'coming back into its own' simply because it is more economical than the motor in making short runs from house to house in the case of delivery carts, &c. There is a good market all over Australia for the utility horse, suitable for artillery and light transport, while the good boned light horse, suitable for the baker's cart, is practically unprocureable. There is still a sufficient number of horses bred in Australia annually to meet all requirements, but the breeding is so neglected, and the selection of mares and horses so carelessly made, that there is a rapid deterioration taking place in the type and class of horses bred. The Australian saddle horse, which has become famous throughout the world, owes its name to the early breeders who demanded the very stoutest of thoroughbred blood to mate with their mares, and many of the best horses to-day still have strains of that blood. It is only by going back to the methods of our early breeders that we can hope to stem the tide of deterioration, and we should and must adopt these methods at once before all the good mares have disappeared.

"Breeding on Right Lines.—A good price can be obtained for a good horse, and anyone breeding a good, sound horse of the right type need not hesitate to ask a good price, as he will have no trouble in finding a market; but so long as breeding of unsound horses of inferior type, poor quality, and nondescript class continues, so will prices that will not repay the expense of breeding be offered. Now is the time to start breeding on the right lines. Good horses have never been harder to find in Australia, and in a very few years the man who has good horses for sale will be able to obtain almost any price within reason, because the demand is here, and will stay here, if the right types of animal are available, otherwise our chief buyers will have to go to other countries for their supplies, and these other countries are going to a great deal of trouble and expense to improve and increase their horse breeding in order to capture the market which we have held for many years, yet which we do not appear anxious to maintain. It is generally recognised that the best horses for military purposes, and for commercial light delivery classes are bred from thoroughbred stallions and three-quarter or half bred mares. It is fully recognised in this district that the horse is by no means 'a back number,' and farmers and pastoralists would be well advised to give a little attention and thought to the breeding of suitable horses of the types in demand. There is no apparent reason why the conditions in and around this locality should not be suitable for the production and rearing of the animal which has carried us on its back, hauled our goods for thousands of years, and proved itself to be man's staunchest friend throughout the ages." (Secretary, D. Harvey.)

(*Circular 370. Illinois, U.S.A.*)

[By GRACE B. ARMSTRONG, A. MARIE SCHRIEBER, and MARY A. MCPHEE,
of the University of Illinois, Urbana, U.S.A.]

Part I.—General Information.

EQUIPMENT NEEDED IN BAKING.

Before beginning to work assemble in a convenient place all general equipment for baking. Learn to use the minimum for efficient work; too much or too little wastes time and labour. In this manual the equipment necessary for each recipe is listed under that recipe. Following is a list of equipment most often required:—

Measuring cups
Mixing bowls
Teaspoons
Tablespoons
Set of standardized
 measuring spoons
Mixing spoons

Spatula
Knife
Egg beaters
Baking pans
Coarse strainer
Bread board
Rolling pin

MEASURING INGREDIENTS.

Correct measuring is one of the most important factors in making good baked products. Note the directions given below:—

1. All measurements given in standard recipes are level unless otherwise stated.
2. To measure a cupful of a dry ingredient, fill the cup and then level it off with the straight side of a knife.
3. To measure either a teaspoonful or a tablespoonful of a dry ingredient, dip the spoon into the material and level off with the straight side of a knife (Fig. 1). Divide the level spoonful lengthwise with a knife for a half spoonful; divide a half crosswise for a quarter.
4. Always sift flour once before measuring.
5. Do not dip measuring cup into flour, sugar, milk, &c. Such practice not only is untidy but wastes the material being measured and may result in inaccurate measurements. Use a tablespoon or a small scoop to fill the cup.
6. An accurate measure of shortening (butter, lard, or other fat) especially if it is hard, can be obtained by packing it down (Fig. 2). Another method, if a fraction of a cupful is to be used, is the water method. From a full cup of water, pour off a fraction equivalent to the amount of fat to be used. Then put in fat until the water reaches the "full" mark. Pour off the water and you have an accurate measure of fat.

Fig. 1.—Measuring a level spoonful of flour.

Fig. 2.—Measuring a level spoonful of fat.

EQUIVALENTS AND ABBREVIATIONS.

Study the table of equivalents and abbreviations so you will be able to interpret the recipes in this manual.

3 teaspoons (t.)
 16 tablespoons (Tb.)
 2 cups (c.)
 2 cups (c.) fat
 2 cups (c.) granulated sugar
 4 cups (c.) sifted flour
 2 tablespoons (Tb.) butter or fat
 2 tablespoons (Tb.) liquid
 4 tablespoons (Tb.) sifted flour
 16 ounces (oz.)

= 1 tablespoon (Tb.)
 = 1 cup (c.)
 = 1 pint (pt.)
 = 1 pound (lb.)
 = 1 pound (lb.)
 = 1 pound (lb.)
 = 1 ounce (oz.)
 = 1 ounce (oz.)
 = 1 ounce (oz.)
 = 1 pound (lb.)

OVEN TEMPERATURES.

Custards—250°F. Very slow	Bread	} 410°F. Hot
Meringues	Muffins	
Sponge cake	Popovers—425°F. Hot	
Angel cake	Parker House rolls—435°F. Hot	
Gingerbread—350°F. Moderate	Baking-powder biscuits—475°F. Very hot	
Plain cake	Pastry—475°F. Very hot	
Cookies		

ESSENTIAL INGREDIENTS.

Flour, liquid, and a leavening agent are the necessary ingredients for most kinds of baked products. Certain other ingredients which improve the taste and texture are sometimes used. These will be discussed as they occur in the recipes.

DIFFERENT KINDS OF FLOUR.

Wheat flour is generally used in this country for bread making, both because people in the United States think it has a more desirable flavour and because it will make a lighter loaf of bread than will oat, rye, or corn flour. The reason for the latter fact is that wheat contains more gluten than other flours—a substance which gives light, springy bread. One can find out what gluten is like by chewing some wheat grains for a few minutes; the gummy mass left in the mouth is gluten.

The difference in the gluten content of hard and soft wheat flours may be seen by tying a cupful of each in a cheesecloth bag and washing out the starch by holding the bag under running water or by dipping it in a number of waters until the water is clear. The resulting sticky mass is gluten, and the difference between the two glutes may be seen by rolling each into a ball and then stretching it. It will be found that the gluten from the hard wheat is more elastic, can be more easily stretched, and breaks less easily when stretched; in other words, it is stronger than the soft-wheat gluten. The colour of the two also differs; the hard wheat is more yellow, the soft wheat is grey.

In making yeast bread it is desirable to use flour that has gluten of good quality, as it is the gluten which stretches to form a framework for the loaf. For this reason hard-wheat flour is usually preferred for yeast breads. Since a spongy, elastic product is not desirable in making quick breads, cakes, and pastry, soft-wheat flours are preferable. Soft-wheat flour, unless it is too soft or has gluten of poor quality, may be used for yeast bread if properly handled. Millers, recognizing this fact, are producing flours which are labelled "all purpose." They are neither strictly hard wheat nor strictly soft wheat but a blending of the two.

A person familiar with flours can easily distinguish between the two flours by colour and "feel." Soft-wheat flour has a tendency to be whiter than hard-wheat flour, the latter being of a creamy colour. Hard-wheat flour is granular and feels slightly gritty. Soft-wheat flour is soft to the touch, and if a little is squeezed in the hand it will retain the imprint of the fingers.

LIQUIDS.

Liquids that may be used for baked products are:—

Whole milk	Water
Skimmed milk	Potato water (yeast breads)
Dried milk	Molasses and syrup

LEAVENING AGENTS.

Mixtures are made light with a leavening agent, which renders them more palatable and more easily digested. There are four types of such agents:—

1. Water expanded into steam, as in popovers.
2. Air introduced mechanically: (a) by beating, as in beaten biscuits; (b) by the addition of beaten eggs, as in sponge or angel food cake.

3. Carbon dioxide from soda plus acid (sour milk, for example), as in muffins or biscuits.

4. Carbon dioxide from yeast, as in bread.

Water Expanded into Steam.—When water is heated to the boiling point it expands and changes into steam. This principle is illustrated in the making of popovers. As the water of the milk expands into steam during the baking, it puffs up the mixture, or makes it light.

Air Introduced Mechanically.—Air also expands when it is heated, and this principle, too, is made use of in making mixtures light. Air may be introduced into a mixture either by long beating or by adding beaten eggs. This air expands, when heated, to several times its size, and in so doing makes the mixture light.

Action of Soda with an Acid.—When acid and moisture are added to soda, tiny bubbles of gas are formed which try to escape; and in forcing their way to the top, they are caught and baked in the mixture. These bubbles make the finished product light, porous, and larger in bulk. Examples of this are baking powder, which is soda and an acid, and soda used with sour milk or molasses. The gas that is formed in both cases is called carbon dioxide, which is the leavening agent.

Yeast.—Yeast is a very small plant that requires warmth, moisture, and food for growth. These requirements are met in making bread; the yeast uses for food the sugar which is added; the milk or water furnishes the moisture; and during the process of making, bread is always kept warm. As the yeast grows it produces a gas (carbon dioxide), which accumulates in small bubbles. The gluten in the dough stretches and confines these bubbles and prevents their escape. This causes the mixture to rise and become light. There are three kinds of yeast:—

1. *Compressed Yeast.*—This is the most convenient and reliable type of yeast if it is fresh. It consists of active yeast plants. Since these plants are already in a vigorous, active state when added to the dough, they begin to grow and multiply immediately, thus shortening the time of the process of bread making. The disadvantages are that compressed yeast keeps only a few days and that it is expensive if large quantities of bread are to be baked.
2. *Dry Yeast.*—Yeast is mixed with corn meal or some other similar ingredient, pressed into cakes, and dried. The drying kills part of the yeast plants, but some live in an inactive state and will grow if given the proper conditions which, as already stated, are moisture, food, and warmth. These yeast cells are not in so vigorous a condition as are those in the compressed cake so the action is slower. The advantages of this kind of yeast are that it will keep for weeks and is cheaper than compressed yeast.
3. *Liquid Yeast.*—This yeast may be made at home if desired, but it requires much care and attention and is not recommended for beginners.

EFFECT OF VARIOUS INGREDIENTS.

Sugar.—Sugar acts as a liquid, improves the flavour, and makes a finer texture in the baked product. The use of too much sugar results in a heavy, sticky consistency and may be the cause of a cake falling. *Cane* and *beet sugar* are chemically the same and may be used interchangeably. The difference in quality sometimes found is due to a variation in the market grades; poor quality may be found in sugars derived from either cane or beets.

Brown Sugar is cane sugar which is not highly refined. It contains a small amount of acid, and when a quantity is used in a cake, soda is added to neutralize the acid, usually about $\frac{1}{4}$ teaspoon to 1 cup of brown sugar.

Pulverized, or confectioner's, sugar is made by grinding and sifting cane sugar. Cornstarch is sometimes added to prevent lumping. Powdered sugar is made in the same way but is not ground so fine. Both make a very close-grained cake.

Molasses is the "mother liquid" from which sugar has been crystallized. It is frequently used as a substitute for part or all of the sugar called for in a recipe

and also serves as a liquid. One cup of molasses is equivalent to $\frac{1}{3}$ cup of sugar and one cup of liquid. Molasses contains some acid, the amount depending upon the way it is manufactured. Canned molasses may contain little or no acid. Sometimes syrups are used for their distinctive flavour, as maple syrup, cane syrup, sorghum, and corn syrup.

Fats.—Fats act as a liquid and serve to make products tender. They also prevent the products from drying out quickly. The kinds of fat which may be used in baking are *butter* and *butter substitutes* such as lard, oleomargarine, the commercial combinations and preparations of fats, and *clarified meat drippings*. Butter is only 85 per cent. pure fat, the rest of the contents being casein, salt, and water. When substituting other fats for butter, therefore, a smaller amount of the substitute should be used and a little salt added. In general, the rule is to use 2 tablespoons less of lard or other pure fat per cup of butter required.

Eggs.—White of egg is composed of albumin, which thickens readily as it cooks. This thickening is called coagulation. While eggs may seem to add moisture to the unbaked product, they act as a thickening agent when the batter or dough is baked. As a leavening agent they affect the texture of the product.

Flavouring.—The enjoyment to be had from eating cake or dessert is due largely to flavour. A natural flavour is better than a commercial extract. Chocolate, spices, dried fruits, nuts, and grated orange or lemon peel make the product delicious and also change its texture. Vanilla, lemon, and other commercial flavourings lose some of their flavour through evaporation when heated.

Other Ingredients.—Chocolate contains a hard fat which adds a little richness but which tends to make the cake stiffer as it dries out than it would be without the chocolate. It also contains starch, which thickens the baked product; consequently in adding chocolate to a recipe for white or plain cake, or cookies, one teaspoonful less of flour is needed for each square of chocolate used. Cocoa may be substituted for chocolate. This should be done by weight rather than by measure; approximately 3 tablespoons of cocoa weigh the same as one square of chocolate.

Fruit adds flavour and moisture to baked products. Raisins or other dried fruit chopped fine give a better flavour than when added whole and also help to retain moisture.

GETTING READY TO BAKE.

1. Study in detail the foregoing general information.
2. *Read the directions in each recipe completely and carefully before starting to mix the ingredients.*
3. Make sure that the oven temperature will be right by the time the oven is needed.
4. Wash the hands thoroughly. Should it be necessary to use a handkerchief or handle the hair while working with food, wash the hands again before continuing.
5. Assemble all utensils and ingredients.
6. Be sure the egg beater is dry.
7. Grease the baking pans if they are to be greased.
8. Sift the flour once before measuring.
9. If the sugar is lumpy, sift it also.
10. Remember that all measurements are level unless otherwise stated.
11. Dried fruit which needs to be cleaned may be washed by placing in a sieve and pouring hot water over it. The fruit should be dried on a paper towel or a clean cloth (an excess of water adhering to the fruit may make the product too moist).

[Part II., which refers to recipes and directions for cooking, will appear in next issue.]

(To be continued.)

WINDOW TREATMENT.

[Paper read by Mrs. A. Anderson at the April meeting of the Kybybolite Branch.]

Centuries back people lived in drafty, windy rooms; in fact the original name for windows was "wind eyes." In order to overcome the draughtiness, hangings were used. These hangings gradually developed into wall tapestries and window curtains of somewhat rude materials. As progress was made in the art of weaving, the rough curtains were gradually displaced by beautiful decorative draperies woven with flowers, fruit, and other attractive designs, which were the forerunner of modern curtains and draperies. Those ancient folk did not enjoy the advantages of a curtain rod, and fastened their window and wall hangings by means of pegs or such like devices. While the people of several hundred years ago must have given some thought to a more improved method of hanging the window decorations of their abodes, advancement towards more convenient and artistic ways of hanging those useful and ornamental home adjuncts was slow.

Window treatment is half the room, and can either make or mar the best furnished of rooms. Many a length of material, of which any artist could have felt justly proud, is wasted through lack of forethought. The greatest innovation and greatest improvement in curtain rods was made during the past half century, the main one being the metal extension rod, to fit different styles and types of windows. Before the advent of the extension rod, the popular window pole, as it was then known, was a 2in. affair, with an end of Rococo pattern. At that time a conspicuous support for curtains rather than one in good taste seemed to be the chief desire. Curtain rods having floridly patterned ends or bright, flashy knobs have practically disappeared except in cases where the rod itself is a beautiful example of craftsmanship, having been replaced with the narrow metal extension rods, except in the case stated. All remember the familiar bamboo or plain wooden pole with brass knobs and brackets, and the simple lace curtains. Only the home of the very wealthy were furnished with draperies beyond those. To-day, the draperies in the average home of people of very limited means outclass, for artistic beauty and attractiveness, the draperies of many wealthy homes of a few decades ago. All this tends towards a brighter home circle, and no home need be drab, for with selective instinct any home can have cheerful harmonious window treatments at the minimum of expense.

Cretonnes, for instance, if selected with judgment, can make one of the most effective of treatments, and need not cost more than from 5s. to 10s., and the idea that one must pay high prices for artistic effects is entirely wrong. The majority of people buy materials without the least thought being given to the surroundings. Blue may be their favourite shade, and blue they must have, even if it should "bark" at the rest of the room for all time. Again, they have a floral wallpaper of fairly bright hues, and must have curtains containing the maximum hues contained in that paper, instead of some quiet subdued colourings, or self tones, which art demands. A tall, narrow window naturally requires a design to flatten it, likewise a flat window requires material to give it height, although this rule does not always apply, for a great deal depends on the surroundings, yet the maxim holds good in nearly every case. One will find a window occupying almost the whole side wall of a room, and yet people will make the mistake of extending the curtains beyond the architrave, thereby giving the room, not only a three-sided appearance, but reducing the apparent size of same. Balance must be maintained, and drapings selected and arranged to fit in and harmonise with each room.

When purchasing curtains, adopt the following procedure:—Get a pencil, writing pad, or sheet of paper, and a measuring stick or tape. Sketch a rough plan of the window to be draped. Measure very carefully, even to $\frac{1}{4}$ in., the outside width and length of framework. Then sit down on a chair facing the window, but at the opposite side of the room; visualise how wide and how long the curtains should be to fit in with the type of window and size of room, taking the size and style of furniture into consideration. If advantageous to extend the curtains beyond the architrave, then measure how far out your eye tells you it should be, likewise the length required, and note on the paper the additional width and length. Then add the quantity required for hems, and purchase only the exact length required. It is foolish to purchase 2½ yds. for each drape if 2in. less will do. Then return to the chair and study the walls, floor coverings, and furniture, &c. Make a note if a floral, stripe, plain, or check effect is likely to prove most suitable. Then note the predominating colours in the room. With this information half the work is done, and the information will eliminate the waste of a lot of valuable time and worry, and certainly go far towards ensuring a satisfactory and pleasing result. The almost endless variety of draping fabrics on the market at the present time provides a very interesting study, and affords the decorator great latitude in the production of artistic effects.

Great attention should be paid to the selection of materials, and suitable materials are those which are of the same character as the other furnishings of the room; for—

instance, checked gingham may make fascinating curtains for a child's room or kitchen, but would be unsuitable for a formal living room. Large pattern cretonne is not suitable for a small room. It is effective only when used in a large room with dignified furnishings. In a room with a great variety of furniture or figured wallpaper, plain draperies or those with unobtrusive patterns are most suitable.

Fastness to light and washing should be taken into consideration. Some dyes are fast to light yet not fast to washing, and *vice versa*, although to-day one has little to worry about dyes, which are generally fast to both light and washing. If in doubt get a sample of the material, and place under a piece of glass, half of which is painted black, or covered with black paper. Place it where the full sunlight strikes for a day, or two days for preference. The part of the material under the black strip will remain the original colour, the part exposed to the sun will show the amount of fading, if any.

The foundation of successful, artistic room furnishings rests to a large extent in the attractiveness of the draperies. Apart from the style and designs of the draperies, colour is the most important factor. Modern wall coverings and decorations are usually more or less neutral, throwing the weight of colour requirements to a very large extent to the draperies. A careful study of colour analysis is necessary to secure correct colour combinations for draperies that will be in harmony with the other furnishings. What is the use of beautiful fabrics if their colour value in relation to the room in which they are to be hung is not studied?

Red, blue, and yellow are the three primary colours. Green, orange, and violet are known as secondary colours. Other colours are obtained by mixing the three primary colours in many and various ways. The best way of selecting the right colour scheme is to decide upon the leading colour. After the colour or tone has been chosen, decide whether quiet or bright tone effects are desired. Quiet tone effects are arrived at by choosing similar colours. Then the colour scheme will remain within one colour family by mixing the leading colour with white, black, or some other primary colour. Bright colour schemes are produced by relying upon contrasting colours placed side by side. Contrasting colours are red and green, orange and blue, yellow and black. Contrasting colour schemes are more difficult to carry out, because they demand a correct sense of their true balance in the room where the curtains are to be hung, but with patience and observation, anyone can accomplish the task.

For decorative purposes colours are classified "warm" or "cool." Red and yellow are the warmest colours, and blue the coolest. Grey is neutral, and may be made either warm or cool by tingeing with colours of either class. Thus we may have pinkish grey or yellowish grey, which are warm, or bluish grey or greenish grey, which are cool. The same method may be used to modify any other colour. In deciding whether warm or cool colours should be chosen, take into consideration:—(1) The amount of natural light. Rooms facing south or shady rooms a substitute for sunshine is required in warm, cheery colours, preferably light tones. Sunny rooms demand cool colours, preferably medium dark, except in bedrooms. The use of very light colours in a sunny room produces a glare, which is a severe tax on the eyes and nerves. (2) The size of the room is an important factor, and demands a variation from the rule; a warm colour tends to make a room appear smaller, this effect is accentuated in proportion to their brightness. Cool colours make a room appear larger, and this effect is increased in proportion to their lightness and delicacy. A dark ceiling causes a room to appear lower, a light one higher.

In planning a colour scheme take into consideration such items as, say, a fine carpet or rug, a cherished picture, or a valuable piece of pottery, whose colour may be taken as the keynote of the room, the other furnishings being planned to lead the attention up to the treasured object, and show it off to the best possible advantage. The majority of people, in furnishing a room, start off by purchasing, say, the floor covering, or having the walls done, and then find no end of trouble awaits them in finding the other items, such as a suite, or curtains to harmonise, therefore, to obtain a successful scheme, it is necessary to complete the whole plan on paper before purchasing. A safe plan is to follow a happy medium between the use of too few and too many colours. A room all grey, or all brown, or all green, is monotonous and depressing, especially when nearly everything in it is of about the same tone, but on the other hand, if several colours are given equal importance, the result is lacking in unity and repose. One way is to follow the example set by the designers of carpets, who allow only one, or at most two colours to predominate, but at the same time give variety and brilliancy by introducing from one to a dozen additional colours so skilfully subordinated that the effect of unity is not impaired, and we speak of a carpet as blue, or green, or brown, or whatever the predominating colour may be.

There are quite a variety of window types, each demanding different treatment, and even two of one type may necessitate quite different styles, as the interior or exterior of the room may have such an influence on the window as to necessitate entirely opposite schemes, therefore, because a window is a certain shape and size, it is

not practicable to say that all windows of that size and type must conform to one set style of drapery. The outside view, the extent of inside privacy, the architecture of the window, and the decorative effect desired, determine the character of the draperies to be used—whether they are to be simple or elaborate, long or short, to hang straight, or to be draped black. Be careful to have the curtains reflect the colours used in the floor coverings and upholstery materials, otherwise the window treatments stand out in vivid contrast and clash with the wall decorations. Double windows, or windows in groups of three or more, admit much more light than single windows, which make it necessary to give the matter of window glare even more serious consideration than in the case of single windows. Valances are desirable in draping double windows; they help to maintain an architectural unity. Draping triple and group windows in the simplest fashion is usually the best. The over-draperies or side curtains may be of the same material as the valances, or any contrasting colours and materials. Bay windows present a draping problem which the home maker finds difficult to solve. The most pleasing and successful way of draping the bay window is to treat it as a single unit, except when there is too much wall space between the windows which form the bay, when each window should be treated as a separate unit.

Casement Windows.—The treatment of this type of window, which may be single, group, or bay type, depends mainly on whether they open outwards or inwards. If they swing in, the variety of treatment is very limited, and the most popular and most practical method is to shirr the glass curtains on rods fastened to the sash top and bottom. When a valance and overdraperies (or side curtains) are used they must be so designed and put up as not to interfere with the inward swinging of the sash. For casements that swing out, it is not advisable to have the curtains attached to the sash; they are apt to be damaged by the weather. For that reason the drapings should be hung from rods attached to the window casings. Over-draperies for casement windows should not come beyond the lower edge of the apron of the window. If there is a seat, it should be upholstered in the same material as the side curtains, if the material is sufficiently substantial. Casement curtains always look more attractive edged with frills, simple fringe, or a gimp or braid. Curtains are the draping of the glass, and over-draperies that which covers the framework, which are better known as side-curtains.

A tendency to-day is to dispense with curtains, and use only over-draperies or side-curtains. This can only apply where the outlook is attractive, such as a flower garden or a pleasing landscape, but where the outlook is not pleasing to the eye curtains are essential. They may be half-sash or full-sash, or hung from a rod inside the over-draperies, but never on the same rod, although expense often demands that they shall. A means of overcoming this difficulty is to hem the curtains and over-draperies as one at the top, allowing them to overlap about 6in. to 9in. according to the size and width of the window. This plan is used with cross curtains, which are hemmed at top in pairs.

Tie-backs.—Tie-backs take various forms and styles, and depend entirely on the window and material used. For light muslins and nets used as a casement treatment, the tie-back must be in keeping, therefore, something light and dainty is necessary, such as a cord or light braid, or a narrow strip of the material used in the curtains, or narrow-shaped tie-backs, frilled all round with a narrow frill about a quarter the width of the frills on the curtains, while for heavy over-draperies the reverse applies. The over-draperies and valance may be of the same material, or of different materials, or may be of similar tonings in a different material, such as the valance in a self-toned cloth, featuring the shade which predominates in the over-draperies. The tie-backs should be of the material of which the valance is made, unless, of course, there is no valance, and then you can use the same material as the over-draperies are made of, and use your discretion as to trimming which will bring out the desired colouring. The tie-backs for over-draperies should be cut boomerang shape, with a lining and semi-stiff interlining. All should be stitched together on the principle of making a mattress, and then turned and finished off. The width is usually from 4in. to 6in. according to the size and type of the curtain, and the length depends on what the window requires. This can be ascertained by tying back with a tape to the desired angle, and then cut accordingly, allowing for hems. The shape of the valance should rule the shape of the tie-back, as any outstanding curves in the valance can be followed in tie-backs in a modified way. Small rings at the ends generally finish the job. Tie-back for centre curtain.

Valances.—Their types are far too numerous to go into fully. Those in general use are Dutch and French valances, pinch-plaited valances, festoon valances, and pelmets. In window draping, valances are preferable in almost every instance, because the valance gives a finishing touch to the window treatment. When side draperies, for instance, which are rather dark hang in long straight folds in a room with two or three windows, they give the effect of sombreness, whereas on the other hand when the line of

colour in the side draperies is connected with the valance, there is a horizontal line which breaks the continuous vertical effect. Without a valance the space between the side draperies gives the window an unfinished appearance. It seems rather illogical to drape a window with coloured side draperies without connecting them with an appropriate valance to complete the job. Like all things, there are exceptions to the rules. Valances can make or mar a room, as, for instance, a window which is set too low to have a full depth valance would be ruinous. The valance in this case should be narrow, and if necessary raised slightly above the frame. Plain gathered valances being easily laundered are best adapted to bath rooms and kitchens, and, in most cases, to bedrooms. Fitted or shaped valances, on the other hand, suggest permanence and dignity, and hence are better suited to the more formal rooms of the house. Midway between the two extremes are the box-plaited valances. Plain gathered valances have a 1in. to 2in. standing heading above the casing. If a different toning to the over-draperies is desired, it is wise to keep the valance dark in tone.

The average depth of a valance is one-sixth of the window height, not the framework. Valances are unlined, lined, or interlined according to the material and type of valance. In making a pinch-plaited valance work on a basis of 6in. for each plait, say five in all, making extra 30in. of material. The space between each plait should be 8in. This is on the basis of 6in. for plaits to 8in. for plain or scallop. This makes 78in. for the five plaits and six plain or scallop. The plaits are drawn together, which reduces the width from 78in. to 48in., the 30in. being accounted for by the five plaits of 6in. each. Further allowance must be made for the side of the rod or board plus turnings, and joins if any. This will appear very intricate, but is actually very simple, although it takes a little time to cut the paper pattern, which is absolutely essential. The width of the valance decides the width of the plaits, but get as near 6in. for plaits and 8in. for plain as is possible.

Pellets are more simple although worked on the same system. Sketch the design, which may follow the frieze of the room in shape, and then work out to scale. Cut the paper patterns from the measurements, and it is a matter then of plain sailing. Old window blinds are ideal for interlining; buckram is too stiff, and liable to get out of shape in a hot climate. Shirred valances are merely French headings on top and bottom with a rod top and bottom to keep valances taut. Festoon valances are also effective. The principle to be followed is to make as if making a pellet, with the only difference that the material hangs in draped curves between two or more points. Usually two for single window, and three for double window can be most artistic with care.

COOKERY AND FLOWER SHOW.

Members of the Parilla Branch of the Women's Agricultural Bureau conducted a successful cookery and flower show in the Parilla Institute on April 19th. This was the third occasion on which the cookery show has been held, and each year is seeing increased success. On this occasion flowers were exhibited for the first time, and a very promising display was seen. Competition was keen in the cookery classes, and left no doubt as to wisdom of continuing these fixtures. There was a very large attendance including many visitors.

The opening ceremony was conducted by Mr. F. C. Richards (Assistant Secretary to the Agricultural Bureau).

During the afternoon the gathering was entertained with a number of appreciative items, which added variety as well as additional pleasure to the function. Those who contributed were:—Miss Sheila McCormack, Peggy Foale, Peggy Dauncey, Maudie Harrip.

Excellent entries were received for the show, particularly in the cookery section. In all, 20 classes were exhibited, and keen competition took place. The judges, Mesdames H. G. Fewings, C. H. Atze, and W. B. Davis, of Pinnaroo, experienced great difficulty in selecting the various winners, due to the splendid class of exhibits. So keenly was the cookery classes contested, that in every one of the 20 shown it was necessary to give second prizes. Several special prizes had been donated, and the committee are indebted to the following donors—Miss Colwill, Mrs. R. C. Kerley, Mrs. H. G. Fewings, Mrs. F. Kerley, and Mrs. H. G. Johnston (flowers). In all, six classes were shown among the flower section,

The following were the results:—Brown sponge, decorated top, Mrs. G. Belling 1, Miss Foale 2; Sponge roll, Mrs. Dabinett 1, Mrs. F. Belling 2; Cornflour sponge, Mrs. G. Belling 1, Mrs. Dabinett 2; Sultana cake, Mrs. Welden 1, Mrs. Brown 2; Coffee cake, Mrs. Colwill 1, Mrs. F. Kerley 2; Ribbon cake, Mrs. Phillips 1, Mrs. Childs 2; Napoleon squares, Mrs. Phillips 1, Mrs. Pearce 2; Scones, Mrs. Bailey 1, Mrs. Johnston 2; Walnut roll, Mrs. Welden 1, Mrs. Howie 2; Cream puffs, Miss Colwill 1, Mrs. Dabinett 2; Puff pastry (Special donated by Miss Colwill), Mrs. F. Belling 1, Mrs.

Pearce 2; Biscuits, Mrs. Howie 1, Mrs. Brown 2; Small cakes, Mrs. Foale 1, Mrs. Dabinett 2; Bread, Mrs. Foale 1, Mrs. Colwill 2; Bread rolls, Mrs. Phillis 1, Mrs. Welden 2; Buns (yeast), Mrs. Phillis 1, Mrs. Welden 2; Rich dark cake (Special donated by Mrs. E. C. Kerley), Mrs. Welden 1, Mrs. F. Kerley 2; Decorated cake (Special donated by Mrs. F. Kerley; Special second prize donated by Mrs. H. G. Fewings), Mrs. Howie 1, Mrs. Brown 2; Jams, Miss Colwill 1, Mrs. Foale 2; Jelly, Mrs. Pearce 1, Miss Colwill 2; Marmalade, Mrs. Foale 1, Miss Colwill 2; Preserved fruits, Mrs. F. Belling 1, Miss Colwill 2; Tomato sauce, Mrs. Colwill 1, Mrs. Pearce 2; Pickles, Mrs. F. Kerley 1, Mrs. Foale 2; Collection of dahlias, Mrs. Welden 1, Mrs. Foale 2; One cut dahlia, Miss Foale 1, Mrs. Foale 2; Sweet Sultans, Miss Dauncey 1; Carnations, Miss Dauncey 1; Gaillardias, Mrs. Foale 1, Mrs. F. Kerley 2; Miniature sunflowers, Mrs. Foale 1.

Junior Section (members under 20)—Miss Foale 1, Miss McCormack 2; (Special prize donated by Mrs. H. G. Johnston).

AUBURN (Average annual rainfall, 24in.).

April 27th.—Attendance, 14.

A THREE-COURSE DINNER.—A number of papers dealing with this subject were read and discussed. *No. 1.—Soup:* Boil 2 knuckles with a gallon of water for a few hours, pour off the liquid, and stand all night. Then skim off the fat, put in a saucepan, and when boiling add an onion cut up, $\frac{1}{2}$ cup pearl barley, salt and pepper to taste. Put a carrot, turnip, and a little of any vegetable through a mincer and add to the soup. Simmer $1\frac{1}{2}$ hours; add a little parsley when serving. *Australian Goose:* Take a leg of mutton, 2 cups of breadcrumbs, a chopped onion, salt and pepper, a little grated lemon rind, 1 dessertspoon of sage (or thyme if preferred), 1 tablespoon dripping, 1 egg, and tablespoon of milk. Bone the leg of mutton and place it flat on the table, spread with seasoning, roll up, and shape like a goose. Sew up with strong cotton, put dripping on top and in dish. Use a quick oven at first. Baste often. Serve with roast potatoes, cauliflower and white sauce, or any other vegetables in season. *Sago Plum Pudding:* Take 1 heaped cup breadcrumbs, 4 tablespoons sago, 1 dessertspoon butter, 1 teaspoon carb. soda, $\frac{3}{4}$ cup each milk and sugar, 1 cup raisins or dates, $\frac{1}{2}$ teaspoon lemon juice. Wash sago and soak in milk, mix breadcrumbs, sugar, raisins, and soda together, melt butter and mix in. Then pour in sago and milk, and mix well.

TOP SPECIAL SUPER

“GIVE IT A SPIN.”

The Adelaide Chemical & Fertilizer Co., Ltd.

Pour into a well-buttered mould covered with buttered paper, steam $2\frac{1}{2}$ hours, serve with sweet sauce or cream. *No. 2.—Pea Soup:* Have ready some stock made from knuckles of mutton. Add to this a finely-chopped onion, pepper, and salt, and thicken with pea meal. Allow it to simmer gently for 30 minutes. Before serving add a little sugar and some finely-chopped mint, and serve with small cubes of toast. *Mutton Pudding:* Cut the meat from a leg of mutton into small pieces. Mix in a chopped onion, salt, and pepper, and (if liked) a pinch of herbs, sprinkle with flour. Make a crust as follows:—Sift 3 cups flour with 1 teaspoon salt, $1\frac{1}{4}$ teaspoons baking powder. Rub into this 3 tablespoons dripping. Mix with water into a stiff dough, turn on to a floured board, and roll out. Grease a large enamel basin and line with the crust, keeping enough to cover the top. Put in the meat, and well cover with cold water. Wet the edges of the crust, put on a round piece to fit the top. Tie a cloth over the basin, and stand in a saucepan of boiling water, and keep boiling for three hours. Young cabbage or turnips are nice with the pudding. *Pudding:* $1\frac{1}{2}$ cups flour, 1 tablespoon butter, $\frac{1}{2}$ cup sugar, 1 egg, 1 heaped teaspoon baking powder, $\frac{1}{2}$ cup of milk. Mix well, and steam in a buttered basin $1\frac{1}{2}$ hours, boiling all the time. Serve with golden syrup or cream. (Miss L. Dennison, Secretary.)

BELALIE (Average annual rainfall, 17.71in.).

April 10th.—Attendance, 26.

A TROUSSEAU.—Mrs. D. Brookes presented the following paper:—“ ‘Trousseau’ is a French word meaning a bunch of keys; a sheaf of arrows; outfit of a lady about to be married; or a girl going to boarding school. The subject of the paper can be divided into five sections:—(1) House linen, which includes sheets, pillow cases, towels, tablecloths, table napkins, and bed covers. (2) Fancy linens, tea cloths, table covers, bedroom sets, d’oyleys, mats, and portieres. (3) Blankets, eider downs, cushions. (4) Personal wear. (5) Useful articles: dish cloths, dusters, peg bags, &c. General observations that must be considered are:—(1) Suitability of purse, the conditions of life, size of the future home, and climate. (2) Quality.—This should always be of the best. It is better to have a few things and good than many and poor. (3) Express Individuality of Owner.—Do not slavishly follow the fashion as fashion alters in household linen, fancy work, &c., as well as personal wear. *Household Linen.*—Have as large a supply of household linen as finance will permit and the best quality available, as there is a great wear on these articles. Pride in a house is aided largely by the kind of linen one is able to possess—dozens of everything if possible; one cannot have too much. Sheets may be linen or cotton according to taste, and pillow slips similarly. Towels should be large and soft, and a few only of the huckaback variety. Have a few dainty guest towels; they are much nicer than a large towel to offer a guest. Tea towels should be of very good forfar, and a large size. Bed covers may be plain or fancy, probably both, and the number according to the number of beds. Tablecloths and table linen are sometimes supplied by the bridegroom, but most girls prefer to choose their own. A few small tablecloths are very handy, and save much work when the laundry is considered. Cheap table linen is never satisfactory. *Fancy Linen.*—A variety is essential. One gets very tired of the same kind of fancy linen. A good supply is necessary, but fashions in fancy goods change very rapidly. Large cloths for supper or small tables are most useful, and one cannot have too many. Here again have a variety. There should not be too many sets for wash stands and dressing tables, but if possible have them to match the colouring of various rooms. Have d’oyleys of different shapes and sizes, but do not make too many. Portieres are very handsome and useful in draughty houses. (3) *Blankets, &c.*—These are sometimes provided by the bridegroom, but the bride usually has a say in this matter, so remember that good quality is essential. The quantity depends entirely on the climatic conditions of the place of abode. For sleep-outs and rougher use a few coloured blankets save labour. Eider downs are very nice, and a real comfort on cold nights, but buy them for use, not show. The better quality are more lasting, hence cheaper in the end, also more artistic. Make plenty of cushions to suit your own taste; also have some useful ones that will stand hard usage. (4) *Personal Wear.*—It is not wise to buy too many clothes; a better plan is to put a fund aside for buying future garments than to buy large quantities to become old fashioned and undesirable. Some girls buy dress lengths and put them away. This may be quite right for cotton, but risky for silk or wool, and dress materials change in style and design. Undergarments should be good in quality and in fairly large quantities. Modern silk underwear obviates the necessity for the elaborate hand-worked garments of earlier times. Have stockings, shoes, and gloves to match the frocks, but again only in moderate quantities. House frocks and aprons are as important as afternoon and evening frocks, so include a few of these in the trousseau, and be neat and attractive. Buy good furs (if means permit) and coats that are not in extreme styles, if they must last more than a season or so. The same rule applies to hats, which should be useful and ornamental. (5) *Dusters, &c.*—Do not forget to provide

a supply of dusters and dish cloths for the new home. A quantity of old white linen or cotton material is useful for many things. If torn into squares and put into a drawer the pieces are ready for use when required. Everything in the final analysis depends on the suitability of everything to the home and life to which the bride to be is going. To buy luxuries where strict economy will be the future lot would be absurd, but good quality fits every sphere. Shun shoddy, though striking articles. A good rule to remember is: 'Buy the most of the best your purse will allow.'" (Secretary, Mrs. A. Cummings.)

COONAWARRA.

April 18th.—Attendance, 37.

RECIPES.—*Bran Biscuits* (Mrs. Alder).—2 cups bran, 1 cup flour, $\frac{1}{2}$ cup sugar, 1 teaspoon cream of tartar, $\frac{1}{2}$ teaspoon carbonate of soda, small teaspoon salt. Enough cream to mix into stiff paste. Roll out, cut into shapes, and bake in moderate oven 20-25 minutes.

Honey Biscuits (Miss F. Jackson).—1lb. sugar, 1½lbs. honey, 4 eggs, 4 teaspoons soda, 2 teaspoons mixed spice, $\frac{1}{2}$ nutmeg, few drops essence lemon, and, if liked, little ginger. Enough flour to roll out. Makes a large number of biscuits; will keep for months in airtight tin.

Walnut Crisps (Miss J. Webber).—Melt 4ozs. butter, allow to cool, but not to set. Add 4ozs. each castor sugar and chopped walnuts, and little essence vanilla. Add 1 small beaten egg. Sift 5ozs. S.R. flour and pinch salt. Form into balls size of walnut and bake in moderate oven about 20 minutes.

Cocoanut Jumbles (Mrs. Hoffman).—Cream cup butter or dripping and 2 cups sugar. Add 2 well-beaten eggs and 3 cups flour, $\frac{1}{2}$ cup milk, $\frac{1}{2}$ teaspoon vanilla. Roll out and sprinkle with sugar and cocoanut. Bake 10 minutes.

Flakes (Mrs. R. J. Childs).— $\frac{1}{2}$ lb. each butter and sugar, 1lb. plain flour, 1 egg. Beat butter and sugar, add eggs and flour. Put through forc. Keeps in shape better if no rising used; 2 tablespoons coffee essence may be used.

Cornfl (Mrs. Len. Redman).— $\frac{1}{2}$ lb. butter, $\frac{1}{2}$ cup sugar, 2 eggs, $\frac{1}{2}$ cup chopped dates, $\frac{1}{2}$ cup nuts, 1 cup S.R. flour. Cream butter and sugar. Add eggs separately, then dates, and nuts and flour. Have cornflakes on greaseproof paper, drop mixture on this in teaspoons. Bake in moderate oven 10 minutes.

Weetie Biscuits (Miss G. Teichelman).—3 cups S.R. flour, 2 cups weeties, 7 dessertspoons butter, $\frac{1}{2}$ cup sugar, 4 eggs. Cream butter and sugar, add eggs separately, then weeties, and lastly flour. Mix well, roll very thin, and cut into shapes. Cook 10 minutes.

Plain Biscuits (Miss G. Teichelman).— $\frac{1}{2}$ lb. butter, $\frac{1}{2}$ cup sugar, 2 cups S.R. flour, 1 egg. Beat butter and sugar to cream, add egg, then flour, mix well, roll thin, glaze tops, and sprinkle with cocoanut. This mixture can be made into:—Shortbread Rounds.—Cut into rounds, cutting a smaller round in centre of half the number. When cooked join together with jam. Cocoanut Tarts.—Cut into rounds, line patty tins, drop in each a little jam, then add filling— $\frac{1}{2}$ cup sugar, 1 cup cocoanut, and 1 egg. Apple Cheese Cakes.—Line patty tins; add stewed apples, mash well, add 3ozs. sugar, 1oz. butter, 2 eggs, 1 lemon rind. Place stiffly beaten egg white on top.

Apple Marmalade (Mrs. Teichelman).—6 lemons, 6lbs. apples, 6 pints water, 9lbs. sugar. Slice lemons thinly; soak overnight in the boiling water. Next morning put on to boil until rinds are tender (about $\frac{1}{2}$ hour). Meanwhile peel and cut up apples. When rinds are tender, add apples and cook until soft ($\frac{1}{2}$ hour). Add sugar and cook quickly ($\frac{1}{2}$ to $\frac{3}{4}$ hour); test after $\frac{1}{2}$ hour. (I use stone pippins to give nice colour).

Quince and Apple Jam (Mrs. Alder).—2lbs. quinces sliced thinly (not peeled), put on to boil with 1½ pints water. When mashed add 4lbs. apples, boil until well mashed, add 5½lbs. sugar. Boil about half an hour. Add another $\frac{1}{2}$ pint water when adding sugar.

BISCUITS.—Paper and recipes supplied by Miss E. Skinner.—Biscuits are a wonderful standby. They are quite easily made. Good ingredients should be used. The biscuits, when prepared, should be put into a very steady oven, and in most cases cooked only until a fawn colour. They should be allowed to cool on the tin on which they have been cooked, and when quite cold stored in an airtight jar or tin. Well made biscuits, if properly stored, should keep for an indefinite period. Biscuits are much nicer if put away in tins for a few days before using. Flavoured icings improve plain biscuits, while rich biscuits are nice with jam between.

Cocoanut Biscuits.—2½ cups flour, 1 cup each butter, sugar, desiccated cocoanut, 2 teaspoons cream of tartar, 1 teaspoon soda, 3 eggs, a little milk. Beat butter and sugar, add eggs, then dry ingredients and milk; roll out thin and bake in a moderate oven 15 minutes.

Shortbread Biscuits.—2 cups S.R. flour, $\frac{1}{2}$ cup sugar, 6ozs. butter, 1 egg. Rub butter into dry ingredients, then add egg, roll out thinly, and cut. Bake in a moderate oven until cooked. This recipe can be made up in several different ways. Makes

very good jam tarts, with a mixt. spread on top of the jam. Also *and 1 egg, green biscuits.*

Cocoa Biscuits.—2 cups flour, 1 cup sugar, 1/2 lb. butter, 2 eggs, 1/2 cup cream of tartar, 1/2 teaspoon soda, 1/2 cup cocoa, 1/2 teaspoon ground ginger. Rub butter into dry ingredients, beat eggs and sugar together. Icing (brown)—2 tablespoons butter, then add 2 tablespoons each boiling water and cocoa, 1/2 cup vanilla essence vanilla, and icing sugar. Spread while hot.

Monte Carlo Biscuits.—1lb. plain flour, 3ozs. sugar, 1/2 lb. butter, 2 tablespoons water. Rub butter and sugar well together with fingers. mix in water, and shake flour in gradually. Rub all together, roll out on floured board to desired thickness, cut into shapes, and mark with the back of a fork. Bake in a quick oven until light brown. Filling.—Make a paste of the following mixture:—1/2 lb. icing sugar, 2 tablespoons butter, 1/2 to 1 teaspoon of vanilla or pineapple essence. When biscuits are cold spread generously with paste and lightly press another biscuit on top. These biscuits will keep a long time in an airtight tin.

Nutty Crunch.—2 cups rolled oats, 1 cup flour or wheatmeal, 1 cup each cocoanut and sugar, 1 eggspoon cream of tartar, 1/2 eggspoon soda, 1/2 cup of any shortening or cream. A little boiling water or milk to mix. Put all ingredients in bowl, rubbing shortening in. If it is cream just stir it in and moisten with a very little boiling milk or water. Knead a little to make pliable, roll out, and cut. Before cutting, take white of egg beaten stiff, enough icing sugar to make stiff icing, flavoured as desired and spread over dough. Sprinkle with almonds, chopped, or desiccated cocoanut, and bake a straw colour in a fairly hot oven. They should have a nutty flavour and be very short.

HOME MADE BREAD.—Paper read by Mrs. Jackson:—"Three essentials to good breadmaking are good yeast, good flour, proper attention and baking. When mixing bread, always see that the bread dish is thoroughly clean and dry; flour should be kept in a dry place. Take 6 sifts of flour, 1 handful of salt, sprinkle salt over flour, and mix thoroughly with both hands. Flour worked in this way makes bread much lighter than if the flour is sifted. Make a hole in centre, put in 2 cups of yeast, have ready 2 dippers of luke wark water, add a little at a time until all the flour is used. Sprinkle some flour on the table from a plate of flour, then put the dough on the floured table and mix thoroughly, adding more flour if needed until it can be rolled on the table without sticking. Put back in bread dish and leave 9 hours to rise. In cold weather I put a sheet of paper on the bottom of the oven and sprinkle a little flour on it, put the bread dish in the oven and cover with two large flour bags, so that if the dough rises over there is no bother in getting the dough off the paper. Have the oven just warm when the bread is put in to rise. When the weather is very hot I put one bag on the bread and leave on a chair in front of the stove. In the morning grease the bread tins, make loaves—using as little flour as possible—put in tins, and leave to rise until the loaves crack on top, then bake 1 hour in a moderate oven. About 1 1/2 dippers of water is needed to mix 6 sifts of flour, so that by having the 2 dippers full there is plenty of water to wash the table and hands, and which saves getting water when the hands are covered with dough.

YEAST RECIPE.—Boil 2ozs. hops in 2galls. of water 1/2 hour. When cool, strain and add 1 pint flour, 1 pint sugar, and 3 or 4 mashed potatoes. When finished fermenting, add a good handful of salt—about 3 days.

Pastry made from yeast dough is very nice. Roll out 1lb. of dough (when fit to put in baking tins), take 8ozs. dripping, spread some over the dough, fold over in three, and roll out again. Repeat spreading and folding 6 times. Then use for covering meat or fruit pies. Eat while hot.

Brownie.—Take about 2lbs. of dough after it has risen. Spread it out on a board or mix in a pan. Mix into it 1 cup of currants, raisins, or any fruit liked, 1 small cup of sugar, a little more than 1/2 a cup of butter or dripping, and a little cut up lemon peel. Knead all together well, adding a little more flour. Put in tins the same as bread. Stand aside to rise, and bake the same as bread in an oven not quite so hot as for bread.

Yeast Buns.—1/2 lb. butter, 1 pint milk (hot). Dissolve butter in milk, 1/2 lb. sugar, 4 eggs (well beaten), 1 large cup yeast, currants, raisins, dates, and peel to taste. Sufficient flour to make a rather soft dough. Mix all ingredients together, let dough rise all night, make into buns in the morning, and bake in a quick oven. Brush over with sugar and milk 5 minutes before taking out of oven. This makes a rich German cake if a softer dough is made.

Yeast Cake or German Cake.—Ingredients: 12 cups of flour, 2 cups sugar, 1 cup cream (1/2 each of butter and lard, or 1 cup of lard will do instead of cream), 6 eggs, 1 teaspoon ground mace, essence of lemon or vanilla, a few sultanas, about 2 cups of milk, 2-tablespoons salt. Sift flour, warm milk, melt butter or lard, beat eggs and sugar with a little warm milk. Make a hole in the middle of the flour, put in all

ingredients, mix with a little warm milk and flour; lastly, put in sponge with some more warm milk (make sponge the same way as for bread). Mix ingredients in gradually; mix well—much softer than bread; cover and put in a warm place to rise for about 3 hours. Then put on well greased slides about an inch thick, using as little flour as possible. Put in a warm place to rise for another hour, then brush over with some melted butter. Put on topping and bake 20 minutes to half an hour.

Topping.—3 cups of flour, 2 cups of sugar, essence of lemon, cinnamon if liked, enough butter to make it crumbly. Put on cake and bake. (Secretary, Mrs. F. Skinner.)

LAURA BAY.

April 10th.—Attendance, 11.

DRESSMAKING.—Mrs. A. J. Bowell contributed the following paper:—“Be sure to take all measurements correctly to ensure a good fit. A person to be measured must stand erect. Tie a piece of tape around the waist, and pull gently into position to make a waist line, because a number of measurements are taken from the waist line.

PARAFIELD POULTRY STATION.

NOW BOOKING ORDERS FOR SPRING, 1934.

EGGS FOR HATCHING AND DAY OLD CHICKENS

WHITE LEGHORNS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, £2 per 100.

DAY OLD CHICKENS.—15s. per dozen; £4 per 100.

BLACK MINORCAS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, £2 per 100.

DAY OLD CHICKENS.—15s. per dozen; £4 per 100.

Free on Rail,
Salisbury.

DELIVERY.—CHICKS—July to September.
EGGS—July to September.

Intending breeders should recognise the importance of establishing their flocks with only the very best of stock also, pay particular care to the size of the egg. The future of the poultry industry in South Australia is almost entirely dependent on the export trade; the size of the egg for export is of the greatest importance. The breeding stock at Parafield is carefully selected and every egg set or sold is of a minimum weight of 2ozs., and a large percentage considerably over.

All Eggs and Chickens sold from Parafield Poultry Station are guaranteed to be produced at Parafield.

EARLY BOOKING IS ADVISABLE.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Flinders Street, Adelaide.

C. F. ANDERSON, Poultry Expert.

Other measurements are the neck, bust, across chest, across back, under arm, sleeve, skirt, and hips, &c. Place all patterns on the material with the centre front straight down the fold of the material, and allow $\frac{1}{2}$ in. for turnings, except for hems and other wider turnings. If the material has a figure or flower design be very careful and watch cutting out; see that the pattern is all running the same way, and that it matches. All cut-out material should be tacked before it is put on the machine to be sewn to keep it all in place, and also to give the desired effect when finished. To secure this great care must be taken from the very beginning of the work; do not slight in the least instance. Handle the work carefully. Each little wrinkle or fold that is carelessly pressed into new material takes away the freshness that is so much desired. Pressing is one of the most essential points in dressmaking. The short, stout person should not wear trimmings or stripes, &c., running around the figure. Trimming running around is most suitable for the tall and thin person. After a garment has been tacked together try it on to see if it fits properly. Never waste scraps in the sewing room, they can be put to many good uses. Never tack up a garment without first pinning it well. When folding material for cutting pin carefully selvedge to selvedge, and two or three places across the width. Both layers of material should be as smooth as possible before laying on the pattern. Care should be taken when laying patterns on the material, and always try to lay patterns so that material is not wasted; it will often come in handy to alter the frock, or perhaps it may be useful to help make garments for kiddies. Keep the machine oiled, but not overdo it or surplus oil may get on the material. Have plenty of pins, a good sharp pair of scissors, and a smaller pair of scissors for cutting cotton, &c., also a good measuring tape." (Secretary, Mrs. D. Morrison.)

McLAREN FLAT.

May 13th.—Attendance, 15.

A tatting demonstration was given by Misses Bell and Nicolle. The remainder of the meeting was occupied with a Question Box.

A successful dahlia show was held in the Institute on April 7. Mr. F. C. Richards, of the Department of Agriculture, opened the function. Mr. R. Elliott judged the exhibits. (Secretary, Miss I. Nicolle.)

MORCHARD (Average annual rainfall, 13.59in.).

May 24th.—Attendance, 24.

BISCUIT MAKING.—Mrs. Lang read a paper on this subject:—"Although biscuits take up rather more time in making than other cakes they keep so much longer, and they are also a great standby for afternoon teas and suppers. Put aside one day a month for biscuit making, then a good supply is always on hand. A variety of biscuits can be made from the one mixture if different-shaped cutters are used, iced in various ways, and decorated. *Foam Biscuits.*—Boil together 1 cup sugar with $\frac{1}{2}$ cup milk, 1 level teaspoon carb. soda, let cool. Take 3 cups flour, 1 cup butter, rub together and mix with the liquid, cut in fancy shapes, and press half almond or cherry on each. *Sao Biscuits.*—2 small cups plain flour, pinch salt, rub in 2 heaped tablespoons butter, mix to a stiff paste, roll out thin, and cut in squares, and prick with a fork. Bake a light brown. Using 4ozs. flour less and adding the same amount of grated cheese makes a nice biscuit to serve for supper with slices of tomato. *Chocolate Mushrooms.*— $\frac{1}{4}$ lb. butter, $\frac{1}{4}$ lb. each sugar and flour, 3 eggs, $\frac{1}{2}$ teaspoon soda, 1 teaspoon cream tartar, 4 teaspoons cocoa or chocolate, 3 tablespoons milk. Put on slide about 1 dessertspoon and bake. When cold ice the top white and underneath light brown. The stalks can be made of white of an egg moulded to shape with icing sugar. *Baskets.*—Make flaky pastry, roll and cut in rounds, and line deep patty tins. Cut thin pieces pastry, twist, and lay on slide in horseshoe shape for the handles. Cream 2ozs. butter, 4ozs. sugar, 1oz. almonds, 3ozs. sultanas, 2ozs. cake crumbs, 1 egg. Half fill pastries, and bake about 20 minutes, handles 10 minutes. Coconut top: $\frac{1}{2}$ cup sugar, $\frac{1}{2}$ cup coconut, 1 egg." (Secretary, Mrs. Schulz.)

PINNAROO (Average annual rainfall, 14.54in.).

The Second Annual Flower and Cookery Exhibition, conducted under the auspices of the Pinnaroo Branch, was held on April 20th. The show attracted a very good attendance during the afternoon, and there were several visitors from Parilla and surrounding districts. Mr. F. C. Richards opened the function.

The arrangements for the show were carried out by the lady members of the Bureau, who proved an enthusiastic body, and threw themselves wholeheartedly into their tasks in order to bring about the success which the show merited. They were headed by Mrs. P. N. Dowd (President) and Mrs. C. H. Atze (Secretary). Their efforts were characterised by a commendable energy and enthusiasm. In Mrs. Atze the members have a very capable and keen officer as secretary, who carried out her duties in an efficient and

thorough manner. In all 134 entries were received. These were judged by Mesdames A. Welden, C. Phillis, and Miss Colwill, of Parilla, and Mesdames Slater and Johnson. Trophies were donated by Mesdames H. G. Fewings, C. R. Mattiske, H. Harding, P. Dowd, — Pearce, C. O'Loughlin, S. Dowd, J. Hannagan, G. McCabe, J. Longford, E. Staker, A. F. Young, C. H. Atze, and Miss G. Harding.

The following was the prize list:—

Cookery.—Loaf bread, Mrs. C. V. O'Loughlin 1, Mrs. C. H. Atze 2; Yeast buns, Mrs. J. T. Longford 1, Mrs. G. C. Pearce 2; German Yeast cake, Mrs. J. T. Longford 1, Mrs. H. Ahrens 2; Six scones, Mrs. L. Vaughan 1, Mrs. Hill 2; Wholemeal scones, Mrs. L. Vaughan 1, Mrs. G. C. Pearce 2; Coffee cake, Mrs. C. V. O'Loughlin 1, Mrs. J. T. Longford 2; Sponge roll, Mrs. G. McCabe 1; Sponge sandwich, Mrs. A. T. Hawthorne 1, Mrs. L. Vaughan 2; Chocolate sponge cake, with butter, Mrs. A. T. Hawthorne 1, Mrs. J. T. Longford 2; Collection pastry, Mrs. C. H. Atze 1, Mrs. H. G. Fewings 2; Jam tarts, Mrs. Hill 1, Mrs. H. G. Fewings 2; Cream puffs, Mrs. G. McCabe 1, Mrs. A. T. Hawthorne 2; Collection of biscuits, Mrs. H. G. Fewings 1, Mrs. J. T. Longford 2; Dark fruit cake, Mrs. J. T. Longford 1, Mrs. G. C. Pearce 2; Currant cake, Mrs. C. H. Atze 1, Mrs. J. T. Longford 2; Sultana cake, Mrs. G. C. Pearce 1, Mrs. C. H. Atze 2; Seed cake, Mrs. J. T. Longford 1, Mrs. C. H. Atze 2; Collection small cakes, Mrs. Hill 1; Plate sandwiches, Mrs. A. T. Hawthorne 1, Mrs. H. Ahrens 2. Pickles, three varieties, Mrs. C. H. Atze 1; Tomato sauce, Mrs. C. H. Atze 1, Mrs. A. T. Hawthorne 2; Chutney, Miss K. O'Loughlin 1, Mrs. C. H. Atze 2; Jam, Mrs. A. F. Young 1, Mrs. Ahrens 2; Marmalade, 1 glass, Mrs. A. F. Young 1 and 2; Preserved fruits, Mrs. A. F. Young 1; 1lb. home-made butter, Mrs. Ahrens 1, Mrs. R. Gilbert 2.

Flowers.—Best dahlias, Mrs. C. H. Atze 1, Mrs. F. Muirhead 2; Six dahlias, distinct, Mrs. A. F. Young 1, Mrs. F. Muirhead 2; Three dahlias, distinct, Mrs. Eley 1, Mrs. F. Muirhead 2; Vase of Chrysanthemums, Mrs. C. H. Atze 1, Mrs. J. T. Longford 2; Vase of cosmos, Mrs. H. G. Fewings 1, Mrs. C. H. Atze 2; Vase Gaillardias, Mrs. C. H. Atze 1, Mrs. A. F. Young 2; Vase flowers, any kind, Mrs. C. H. Atze 1, Mrs. H. G. Fewings 2; Three roses, Mrs. C. H. Atze 1 and 2; Any flower, not previously mentioned, Mrs. H. G. Fewings 1 and 2.

SADDLEWORTH (Average annual rainfall, 19.6in.).

May 1st.—Attendance, 12.

The Branch conducted a cake competition, "Butter Sponge," the successful competitors being Miss Frost first and Miss Coleman second prize. Mrs. Coleman reported having visited the exhibition of women's handicrafts recently held under the auspices of the C.W.A., at Spalding. (Secretary, Miss G. Frost.)

TANTANOOLA.

May 1st.—Attendance, 17.

Miss E. Campbell, of the Education Department, delivered an address, "The Food Value of Milk." The Hon. Secretary, Mrs. Telfer, reported in connection with the S.E. Conference that receipts amounted to £11 6s. 9d., expenditure £10 5s. 4½d., leaving a credit balance £1 1s. 4½d.

WEPOWIE (Average annual rainfall, 12.46in.).

April 24th.—Attendance, 8.

HAND-FEEDING CALVES.—Mrs. H. Noske read the following paper:—"Feeding calves properly is most essential in raising a good herd. A calf that is improperly fed will not develop into a first-class cow, no matter how good it may be when born; it should be let run with the cow for at least 24 hours before being weaned from its mother. The calf should then be put out of sight of the cow. The cow's milk is not good for at least four to six milkings. It is best to feed the calf as soon as possible after milking, because the milk direct from the cow is at the correct heat. It is a good plan to miss one feed, then the calf will readily suck the finger. The fingers of the hand should be placed in the calf's mouth, and then place its mouth in the bucket of milk. Half a gallon a day is sufficient new milk for the first week, when the amount should be gradually increased to 1gall. a day. It is best to feed calves twice a day. A little green grass during the day is much better than feeding on too much milk. The calf will get a good start if fed on new milk for two weeks; then gradually wean it from new to skim milk. By this time the calf should have all skimmed milk. This tends to keep them healthy, free from scour, and very little cream is lost. When there is more than one calf in the yard at feeding time stalls should be built to separate them while drinking. Every calf should have its own drinking vessel to enable it to have the same amount of milk. If this is not done the calf that can drink the fastest will get more milk than one that drinks slower. Kerosene tins cut in halves make excellent drinking vessels for calves. The calves when drinking

should be bailed until all desire for sucking has passed. Calves if not kept apart in some way or other will certainly suck one another, which tends to spoil the shape of the udders, and is liable to injure them. All calves should have access to a small, green paddock where they are able to run about and pick grass if they so desire. A shed should be provided to house calves during wet weather. They should be fed with milk for at least four months before being turned out. If a calf is weak and miserable it may be advisable to feed it with milk a little longer. A calf from a poor milking cow may be reared to become a profitable animal if it is well cared for at the start. If a calf becomes scoured from feeding on skimmed milk, put one handful of flour in the milk and stir well. On no account should a calf be ill-treated; it tends to make them very bad tempered and stubborn. A calf or cow with these faults is a very untrustworthy animal to have about the place, and may as well be sent to the abattoirs." The paper was then discussed. Members did not think it necessary to feed on new milk for three weeks. Meggitt's meal was suggested as a good addition to the milk, which should be scalded and added to the milk. Mrs. E. Knauerhase preferred 1 tablespoon of flour dissolved in cold water, and then hot water added to make it the consistency of starch. She has used this with great success. (Secretary, Mrs. E. Roocke.)

WILLIAMSTOWN (Average annual rainfall, 27.77in.).

May 2nd.—Attendance, 8.

USEFUL HOUSEHOLD HINTS.—Contributed by Mrs. Hamilton:—"When making plain suet pudding add two or three tablespoons of rolled oats to the flour before mixing the pudding will be lighter and more digestible. To prevent cooked beetroot from becoming mouldy, place a little prepared mustard in the jar in which it is kept. If a dish sticks to table baize, do not attempt to pull it off. Instead, fill the dish with hot water and leave for a minute or two; the utensil can then be lifted without leaving a mark. Before washing coloured towels, table cloths, &c., set the colours by pouring boiling water over them, then wash as usual. This will obviate any likelihood of the dye coming out and spoiling other clothes. A teaspoon of orange juice added to tomato soup will greatly improve the flavour. If voile and crepe de chine frocks are hung out without wringing they will never shrink. To remove coffee stains from material, apply to the stain the yolk of an egg mixed with a little water and allow to dry. Rub out before washing. Kerosene applied quickly to a burn will relieve pain and often prevent a blister. To prevent pastry at the bottom of fruit pies or jam tarts from becoming heavy and sodden, brush over the pastry with a beaten egg white before putting in the fruit or jam. When washing out tea towels, do not rinse in clear water but wring them with the hands out of the soapy water and hang them on the line. By this method they remain beautifully white. To keep away moths insert cloves thickly into the skin of a ripe orange, set it in a cool oven until the skin is dry then place it among blankets or furs. Sago soaked in water until quite soft is an excellent substitute for suet in boiled puddings. Use in the proportion of 1 part sago to 4 parts of flour. When stewing prunes add a small teaspoon of lemon juice to the stewing water. The prunes will then have a smoothly and finer flavour. (Secretary, Mrs. Cundy.)

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Bureau Conferences.

District Conferences will be held as follows:—

Murray Lands (West), at Karoonda (Nunkeri Branch), Tuesday, July 31st, E. R. Peltz, Nunkeri (Secretary).

Southern, at Strathalbyn, Thursday, August 16th, F. W. Allison (Secretary).

Hills, at Coromandel Valley (Blackwood Branch), Thursday, August 23rd, H. Goldsack, Coromandel Valley (Secretary).

Eyre's Peninsula (Southern), at Yeelanna, Wednesday, September 5th, R. R. Wilson (Secretary).

Eyre's Peninsula (Central), at Kyancutta, Friday, September 7th, E. A. Kelly (Secretary).

Pinnaroo Line, at Pinnaroo (Parilla Well Branch), Tuesday, September 18th, E. C. Slater, Pinnaroo (Secretary).

Murray Lands (East), at Caliph, Thursday, September 20th, W. H. Todd (Secretary).

Fruit (Non-irrigated Districts), at Balhannah, Tuesday, November 6th, C. G. Grasby (Secretary).

In each case the Conference will commence at 10.30 a.m. Members of Branches are invited to submit papers and questions for the agenda.

Agricultural Shows.

We have been advised by Secretaries of Agricultural Show Societies that their shows will be held as follows:—

Maitland, Wednesday, September 26th.

Denial Bay, Friday, September 28th.

Gawler, Saturday, September 22nd.

Jamestown, Wednesday, October 10th.

Karoonda, Wednesday, October 3rd.

Loxton, Wednesday, October 10th.

Burra, Wednesday, October 24th.

Minlaton, Wednesday, October 24th.

Mount Gambier, Wednesday and Thursday, October 24th and 25th.

Murray Bridge, Thursday, October 25th.

Woodside, Saturday, November 3rd.

Cancellation of Stock Brands.

In accordance with the provisions of section 53 of the Brands Act, 1933, the Registrar of Brands (Mr. H. O. Laurenti) states that on and after January 2nd, 1935, the registration of all brands and marks which were registered prior to December 31st, 1934, will be cancelled unless the owners give notice in writing to the Registrar that they wish to retain the brands registered in their names. No fees are required when giving such notice. If an acknowledgment of the notice is requested, however, a stamped addressed envelope must be enclosed.

Any person who has already applied for brands or marks to be retained need not comply with this notice.

Readers will facilitate the operation of these provisions of the Act if they will advise others, and Branch Secretaries are requested to bring the matter under the notice of their members at an early meeting.

Mr. Laurenti proposes to send a "poster" to each Branch with a request that the Secretary display it in some conspicuous part of the township.

Are You a Member?

It pays to be a Member of the Society. There is considerably more in this than the personal gain of being able to visit the Show when you so desire. Your Membership means a personal interest in the activities of the Society, which is endeavouring to improve every phase of primary production of the State.

The subscription is £1 1s. per annum, for which a Member is entitled to Tickets of admission to the Show for himself and two ladies to all sections of the grounds, including stand reserved exclusively for Members.

**LADIES' TICKETS ARE TRANSFERABLE,
AND WILL ADMIT BOYS UNDER 14
YEARS OF AGE.**

Wheat Qualities.

Reference has been made in recent reports from the Argentine on quality in wheat, and it is stated that certain varieties are being excluded by the Grain Control Board with the object of maintaining the standard of the recognised export type and enabling these to compete in more equal terms with the product of other exporting countries such as Canada. One of the difficulties with which the grain trade has had to contend in the past in this country has been the tendency of the wheat grower to favour varieties which yield heavily, regardless of quality. The inauguration of the Grain Control Board offered a splendid opportunity to take steps to combat the evil, and it was decided to exclude certain varieties in the area tributary to Rosario and the neighbouring ports. At the same time it was decided to form a new grade, to be known as No. 3, in the composition of which these varieties would be permitted and which would be quoted at a discount under No. 2 for this crop year. No. 3 is not permitted to be mixed in with Nos. 1 and 2, under penalty of losing their grade. In a country which has no official grading system, this latter provision is not very easy to enforce. But a great deal of good can be effected by propaganda, and in the meantime there is little doubt that the Grain Act now before Congress will provide the necessary compulsory powers before another crop year comes round, even though the mechanical equipment may still be lacking. Meanwhile, a National Wheat Commission has been called into being and charged with the investigation of the matter of inferior wheats. It reports that there are no less than 6½ million acres on which wheat is being grown which is unfit for exportation. The list of undesirable types is expanded to a list of 24. The Commission has divided the cereal region of the Republic into zones, for each of which it recommends certain high grade pedigreed strains of proved adaptability to each zone.

Obviously it is not possible to provide pedigreed seed for more than a fraction of the acreage where it is needed. But the Grain Control Board has undertaken to collaborate by placing at the disposal of the Ministry of Agriculture whatever parcels of suitable wheat fit for seed which come into its possession, and the Ministry is proposing to exchange such seed for wheat of the inferior types which would otherwise again be sown. By this means, it is hoped to do a good deal to eradicate the objectionable types now being grown and effect a distinct improvement in quality of the Argentine wheat exported. It is calculated that there are about 275,000 bags of pure seed wheat available in the various experimental farms, private and official, of the Republic, most of which will be sold in small parcels to individual farmers desirous of sowing a few acres in order to provide a quantity of seed for the following year. In this connection, a plan adopted in the important wheat-growing province of Cordoba is of great interest. In these times of low prices few individual farmers can afford to purchase the expensive pedigreed seed they would like to sow. So the provision of the seed wheat has been undertaken co-operatively. On some of the large estates which have been "colonized," the proprietor or the administrator has been induced to purchase seed which is entrusted to the most capable of the colonists to sow, with the condition that the product when threshed is to be exchanged, bag for bag, on equal terms, with the other colonists for their ordinary wheat to the extent calculated as necessary to provide seed for the following year. In districts where this plan is not possible, it is being attempted to organise the farmers into groups to co-operate by making an individual contribution to the cost of the seed, and select one of their number to act as "seedsman" and undertake the growing of the wheat, distributing the product along the same lines. In each case the arrangements are supervised and the necessary instructions are given to the "seedsman" by a representative of the Provincial Department of Agriculture, who also inspects the growing crop and superintends the exchange of seed for wheat after threshing.

Publications Received.

The Library of the Department of Agriculture acknowledges the receipt of Bulletin No. 75, "Poisonous Plants on the Farm," by H. C. Long, issued by the Ministry of Agriculture, England. Price, 2s. net.

AGRICULTURAL INQUIRIES.

[Replies supplied by Mr. W. J. Spafford, Deputy Chief Director of Agriculture.]

Agricultural Enquiries from Tumby Bay.

11. "Would it improve a wheat crop in this district to drive a flock of sheep backwards and forwards over it when it is about 4in. high?" Reply—The consolidation of the soil which would result from repeatedly driving sheep over a wheat crop would do it a great deal of good in most seasons in your district, but it would generally be better to do it before the crop reaches 4in. in height. The complete feeding down of the crop after it has grown 4in. would not be a good practice in your district, but so long as the flock was kept moving the quantity eaten would not be sufficient to damage it.

2. "Does Wimmera Rye Grass do well on sandy soil?" Reply—Wimmera Rye Grass does well everywhere that Barley Grass grows strongly. It is easily established by putting a couple of pounds of seed per acre in with a cereal crop which is to be harvested for grain, by throwing some seed on to the superphosphate every time that the seeddrill is filled. Sown in this way it seeds itself for a certainty and when once established remains as an ordinary farm weed.

ORDER NOW.

WALLAROO-MOUNT LYELL FERTILISERS, LTD.,
Wallaroo and Port Adelaide.

What is Fallow?

The Secretary of the Warramboe Agricultural Bureau asks what is the definition of fallow. Reply—The term "Bare fallow," as used in Australia is usually applied to land which was ploughed or cultivated in the winter, kept free from weeds, and loose and open on the surface throughout the spring and summer, to be seeded in the following autumn or winter. If the land receives its first stirring at the end of summer and is kept loose and free from weeds for 13 to 15 months before it is seeded it is generally known as "Summer fallow." If the original stirring is not given until the spring, about 6 to 7 months before seeding the land, it is usually spoken of as "Late spring fallow." Grass land stirred up in late summer or early autumn to be seeded the same year is not bare fallow in any sense of the word as used in Australia.

Control of Wild Oats.

"Mannum" asks: "*Would it better to sow wheat immediately after rain comes and risk a strong growth of wild oats, or wait about a week, cultivate to a shallow depth, with wide shares, and then sow?*"

Reply—If Early Gluyas or Waratah wheat is to be sown, wait until the oats have germinated, cultivate, and then seed, but with most of the other popular varieties of wheat seed as soon as it rains, using more seed than usual and risk the damage to be done by the oats. The correct way to tackle wild oats as seeding time approaches is to get them germinated, cultivate them out, culti-pack or roll the land, sow the seed and culti-pack or roll again. Under conditions obtaining at Mannum it is as well to use wheats like Early Gluyas or Waratah, so that seeding can be delayed a little longer.

Wheat Varieties for Stubble Land.

Bundaleer Springs Branch of the Agricultural Bureau asks for the names of varieties of wheat suitable to sow on stubble land.

Reply—Most varieties of wheat which germinate quickly and immediately commence to make strong growth are suitable for sowing on stubble land. Of these varieties Early Gluyas has proved the best for the purpose, but Waratah is also very promising, and King's White is really useful. Any of the above wheats can be sown with perfect safety well on in June in the Bundaleer district. Full success with cropping wheat the second time depends upon—(1) Securing a good stubble burn. (2) Cultivating or ploughing the land as soon after the burn as possible. (3) Cultivating or ploughing to a very shallow depth. (4) Using an early strong-growing variety and delaying seeding to suit the variety.

High Bunches of Cereals in Stubble Crops.

"Black Springs" asks: "*What is the cause of high bunches of cereals seen in stubble crops?*"

Reply—The high bunches of cereals frequently seen in crops sown on stubble, if not due to the presence of self-sown plants which germinated some time before the sown seed—as is a common occurrence—are obviously caused by greater fertility at the spots where they occur. As a rule this greater fertility is derived from the droppings of animals, and the principal plant food leading to the greatly increased growth whilst the cereal plants are young is—in all probability—nitrogen. In well-fallowed land there is generally sufficient nitrogen at seeding time to lead to full growth of all of the young cereals, and so the presence of the droppings of animals is not noticeable in the crops, but the position is quite different in stubble land, particularly if the soil is not in really good heart, because the crop used up the available nitrogen and relatively small amounts are collected and held in the soil until the soil is moist and warm at the same time. This need of moisture and warmth together seems to explain why it is that in some seasons this clumpiness only lasts a short time, whilst in other years it persists until well on into the spring.

HORTICULTURAL INQUIRIES.

[Replies supplied by Mr. G. QUINN, Chief Horticultural Instructor.]

Treatment of Green Aphis of the Peach Tree.

The prevalence at the present time of the over-wintering eggs of this very injurious pest on the fruiting twigs of peach trees has been reported to the Horticultural Branch of the Agricultural Department from various fruitgrowing centres of the State.

Experiments carried out over several seasons at the State Orchard at Coromandel Valley, near Blackwood, and verified by more elaborate trials made in New South Wales and Victoria indicate that the tar distillate sprays are the most effective spraying remedy we have yet used against this pest. It is used as an ovicide in mid-winter whilst the peach trees and the pest are quite dormant. Those peach growers who have been troubled with this pest should not apply this spray later than the end of July in most districts of this State, otherwise risk of injury to the buds and bark may be expected. Growers have been informed from various sources that even when used during the most dormant stage of the trees these tar distillate washes will seriously damage the bark of the last summer's shoots. The Chief Horticultural Instructor (Mr. Geo. Quinn) reports that he has not heard any statements relative to its injurious effects on peach trees in New South Wales and Victoria when it has been used in the middle of winter, and the Manager of the Government Experiment Orchard near Blackwood (Mr. R. Fowler) assures him he has been unable to detect any evidence of injury arising from the use of several brands of the tar distillate sprays on the test trees treated with them during mid-winter in the Experiment Orchard during the past couple of years.

(River Murray Conference.)

Dusts v. Sprays.

"Have any tests been conducted in the River areas with the object of proving the comparative value of dusts versus sprays in the control of disease in vineyards and orchards, and if so, what results were noted?"

Reply—I have no knowledge of any carefully controlled tests having been made in the Murray Valley to determine the comparative values of dust sprays and liquid sprays for the suppression of diseases and pests commonly found in the orchards and vineyards in the irrigated areas.

At Blackwood Experimental Orchard tests have been made between arsenical dust sprays containing arsenate of lead powder and arsenate of lead powder in the form of liquid spray. The evidence showed that the protecting powers of the liquid form far exceeded that of the dust spray in so far as codlin moth attacks were concerned.

Further, in respect to the curl leaf fungus disease in peach trees, the prepared copper dust sprays give infinitely less protection than the liquified forms known as Bordeaux Mixture (copper sulphate and lime) or Burgundy Mixture (copper sulphate and carbonate of soda crystals).

At Hackney Road, Adelaide, Experiment Orchard, lime sulphur liquid spray controlled the oidium or powdery mildew in grape vines much more effectively than sulphur dust sprayed on dry with a Niagara dust gun. This was particularly outstanding when the early summer remained cool.

For some pests in vegetables, the market gardeners around Adelaide find nicotine and arsenate of lead applied as dust sprays very effective against aphides and leaf wigglers (cabbage moth caterpillars) respectively. Celery growers have also found some measure of protection to their plants against the leaf spot fungus (*Septoria apii*) by the use of copper dust sprays, but there is some reason—from a few tests made with liquid copper sprays (Bordeaux or Burgundy) for believing they are superior in their action.

The application of the dust sprays is a cheaper and more rapid process, but the efficient distribution of the dusts to the under parts of the leaves and fruits attained by liquid sprays is rarely possible of achievement with the dusting appliances thus far available.

(*River Murray Conference, Barmera Branch.*)

Green Manure Crops.

"How do rye and oats compare with peas or beans as green manure crops?"

Reply—Thus far, the comparative values of cereal crops—rye and oats—with those of peas and beans as a means of green manuring the irrigated lands in the Murray Valley have not, to my knowledge, been tested. This season, a number of growers in the various settlements are trying rye as a green cover crop, and the crops are giving good promise thus far. It is claimed that these cereals will produce a greater weight of green growth than will the legumes—peas, beans, tares, or lupins. Further, that the rye will grow more quickly during the cold season than the legumes mentioned.

In discussing the use of crops for green manuring purposes it should be remembered that they return organic matter containing only the same quantities and kinds of mineral substances drawn from the land and carbon acquired by the plants from the atmosphere. The legumes return all of these with additional nitrogen which is collected for them from the atmosphere by the bacteria which attach themselves to the roots of the legumes. Whilst we do not know what proportion of the nitrogen was extracted from the soil by the plants themselves, we have found that a crop of an acre of beans 6ft. tall, grown at Berri Experiment Orchard, contained in its roots and tops the equivalent of nitrogen to that found in a dressing of over 8cwts. of sulphate of ammonia per acre. A good crop of field peas returned a slightly lesser quantity of nitrogen per acre. It will be seen, therefore, that if equal areas of cereal crops do not yield an outstanding greater weight of organic matter than the beans or peas, the effect may be offset by the discrepancy above referred to. It is true, that at the outset organic matter may be most desirable, but crops of beans such as are produced annually at the Berri Experiment Orchard introduce large volumes indeed of this soil correcting factor.

It is claimed that rye crops will develop rapidly and reach large dimensions of growth in time to be ploughed under before the roots of the trees or vines start into activity, and are likely to be injured by the ploughing or the decaying of the green vegetation. Our experience at the Berri Experiment Orchard indicates that, providing the crop is got in early in March and given a good start, the same may, with equal force be claimed for the beans, which have often been ploughed under at the end of July and early August.

VETERINARY INQUIRIES.

[*Replies supplied by Veterinary Officers, Stock and Brands Department.*]

Currency Creek asks treatment for lice in horses?

Reply—A liberal application of raw linseed oil over the whole of the body will kill the lice, and dressing should be repeated in five to seven days. The effect of the oil dressing is to clog the breathing pores in the body of the louse, through which it breathes, so that it dies of suffocation.

Manoora reports pigs with scaly-like condition of the skin, the animals are continually rubbing themselves.

Reply—The skin trouble with the pigs is probably due to digestive disturbance. Once a week give a dose of 2ozs. Epsom salts per pig in a little swill feed. Reduce the daily amount of grain fed somewhat, and, if possible, let the pigs out for part

of the day to graze. Give 1 teaspoon per pig of the following mixture daily in the feed:—Salt, 1 part; air slaked lime, 2 parts; sterile sweet ground bone meal, 2 parts. Wash the skin well with warm soapy water with a little washing soda dissolved in it. Then, after drying, smear lightly with flowers of sulphur, 1 part; lard, 4 parts. Two or three dressings of this applied twice a week should be sufficient.

Mount Hope asks for treatment for worms in pigs.

Reply—The large white worms in pigs can be eliminated by giving one dram (one teaspoonful) of oil of turpentine in 4ozs. of castor oil per 100lbs. live weight (increase or decrease doses according to weight). Starve pig for 12 hours before giving. The droppings should be collected and burnt. Treatment alone is not satisfactory, as re-infestation soon occurs, pigs becoming infested by taking in eggs in their feed. For this reason the piggery should be cleaned out and repaired (especially floors) if necessary. Further, if removed to fresh ground, the pigs will do much better. Young pigs are chiefly affected, and special attention should be paid to them.

Hon. Secretary, Agricultural Bureau, Rendelsham, asks the age at which a sheep is considered full grown?

Reply—A sheep is full grown when the eight permanent incisors are through and in wear. Under Australian conditions this occurs between the ages of $3\frac{1}{2}$ and 4 years.

Shoal Bay Agricultural Bureau reports death of 9 pregnant ewes following drenching with bluestone solution.

Reply—From the information and symptoms supplied the sheep died from a condition known as "toxaemia of pregnancy" (twin lamb disease). This disease is always associated with pregnancy, and generally occurs within five weeks of lambing. Ewes in fat condition are generally affected, but occasionally it occurs in poor conditioned ewes. The cause is not definitely known, but is considered to be due to liver changes, which interfere with liver function and consequent circulation of toxins (poison) in blood, normally removed from blood stream by the liver. Affected sheep show the following symptoms:—Stay apart from other sheep and show muscular twitchings of body, principally confined to head and shoulder regions. They may appear to be blind and stiff in their movements. Death usually occurs within 3-4 days of symptoms being first noticed. On *post mortem* the carcass and organs appear normal, but frequently the ewe is carrying two lambs. The liver presents a pale reddish-yellow appearance, due to presence of excess fat in the tissues. Curative treatment has been tried with various mixtures, but with little success. However, preventive measures can be carried out, and these are as follows:—Limit the food supply by placing in paddocks where feed is scanty in order to make the sheep exercise. If feed is plentiful, and this cannot be carried out, the sheep must be exercised daily. Treatment of affected sheep may be attempted, and consists of giving 4ozs. of Epsom salts dissolved in water and adding 4 tablespoonsful of treacle. Give this drench once, and then twice a day smear on tongue and teeth 1 tablespoon of treacle. The fact that the sheep died following drenching is only a coincidence. It is pointed out that bluestone solution, if given in excessive amounts, is an irritant poison, and sheep so affected would not show the symptoms described by you.

Agricultural Bureau, Truro, reports aged gelding with a ravenous appetite.

Reply—The following course of treatment is suggested:—Starve the animal for 36 hours (this is important), but allow water to drink during this interval. Then give the following drench:—Raw linseed oil, $1\frac{1}{2}$ pints; turpentine, 4 tablespoons. Until the purgative effects of this drench have worked off, feed lightly on bran mash or well damped bran and chaff. Then gradually bring animal back on to its customary feed, and give 1 tablespoon of Fowler's solution of arsenic in damped feed night and morning for a fortnight. A fortnight after the completion of this course of treatment repeat the whole treatment again.

SOME POTENTIALITIES OF SOUTH AUSTRALIA.

[Summary of an address delivered to Mount Gambier Rotary Club by W. J. SPAFFORD, Deputy Director of Agriculture.]

It is more than ordinarily pleasing to speak on the Potentialities of South Australia to an audience of South-Eastern people because of the belief that much of the future progress of the State is dependent upon the development of the South-East, and anyone living in that district must be specially interested in the subject.

South Australia is an agricultural State, and as its progress will depend upon the expansion of its agricultural interests, it is the duty of every citizen to help this agricultural progress whenever opportunity offers. This applies with particular force to the leaders in business and the professions, who should never lose sight of the fact that we are likely to remain an agricultural community. We have no manufacturing advantages in South Australia; there is neither coal, water, nor oil for providing cheap power; the climate experienced over most parts of the State is unsuitable for manufacturing the finer fabrics and other articles of high quality, nor is the water sufficiently plentiful nor good enough; and, perhaps more important still, our population is too small to attract manufacturers. Unless special circumstances exist it is usual to manufacture where the bulk of the articles made are sold locally and the surplus exported, and so it is natural for manufacturers to go where the population is densest. It is true we smelt ores at Port Pirie, and make motor bodies for export, but these are practically the only manufacturings of any kind we do which bring in "new" money. We still make some flour, but this only brings about the same amount of money that would have been received for the wheat, the added value for manufacturing being in the by-products, and if these by-products (bran and pollard) were not available we would need to import concentrated foodstuffs for livestock. Other forms of manufacture, like the making of butter, cheese, wine, etc., are quite essential to enable us to sell the rural product.

PROGRESS ALREADY MADE.

Since the commencement of the State in 1837 we have made considerable agricultural progress. Although it often appears as being very slow, it is gradual and continuous with very few sudden improvements, but despite the fact that the march forward was rarely spectacular and appeared sluggish at times, if we look back a few years we cannot fail to see that a very considerable advance has taken place. The rapid forward progression is very noticeable in a young country like our own because of the absence of local traditions which have so frequently hampered conquerors of any country with an old civilisation, no matter how backward.

Progress made is of snowball growth, and is getting greater and greater as time goes on, largely, of course, because the means of disseminating the knowledge gained is improving all the time. In this connection South Australia has been fortunate in the possession of that wonderful organisation known as the Agricultural Bureau, where many of the keener intellects of the agricultural community meet regularly, discuss their immediate problems, and have brought to their notice the discoveries and improvements made in other parts of the State and, indeed, in other parts of the world.

PRESENT-DAY PRODUCTION.

That the progress has been considerable can be realised by remembering that even in times of low prices our production was worth in 1931-32 £26,973,375, of which agriculture provided £19,048,788 or 70.6 per cent.; factories manufac-

tured goods worth £6,570,939 or 24.4 per cent.; mining gave £648,580 or 2.4 per cent.; and miscellaneous articles such as fish, game, &c., were valued at £705,068 or 2.6 per cent.

These figures show the great preponderance of agricultural production over all others, but perhaps the value of agriculture is more strikingly brought out by an examination of the figures showing the overseas exports from the State. The total value of all overseas exports in 1932 was £12,228,312, of which £10,409,453 was received for agricultural products, which equalled 85.1 per cent. of the total; mining returned £1,633,558 or 13.4 per cent., and other articles only £185,211 or 1.5 per cent. Although the figures show 85.1 per cent. for agricultural exports it is even greater than this, because the bulk of the 1½ million pounds shown for mining belongs to New South Wales as it consists largely of smelted ores from Broken Hill which were treated at Port Pirie and then shipped direct from that port.

SOME OBVIOUS DEVELOPMENTS.

Because the part of agriculture which is practised in most of South Australia is similar to that which has persisted for centuries in other semi-arid countries, and is known as "Mediterranean agriculture," it is to be expected that we will continue to produce in ever-increasing quantities wheat, barley, vines (for wine and drying), olives, figs, almonds, sheep, pigs, dairy cattle, and poultry.

Wheat.—We now crop about 4,000,000 acres each year, and the average yield is about 11bush. per acre, and there seems no reason why we should not crop over 5 million acres when prices become normal, and with a thorough cleaning up of land, better fallowing methods, improved varieties, &c., the yield should be raised to about 18bush. per acre per year.

Barley.—About 300,000 acres are cropped annually for a return of about 18bush. per acre, which yield should easily be increased to 25bush. per acre. The area capable of producing this crop, without reducing the area sown to wheat, is enormous in this State, and when we have developed an extensive export trade for pig products, millions of acres will probably be seeded to barley every year.

Vines.—There are 34,000 acres under wine grapes and about 20,000 acres for other purposes, and these areas can be increased to a very great extent as markets expand.

Olives, Figs, and Almonds.—These fruits do really well in this country, and even if it is only to supply Australian requirements a very great increase in production appears inevitable.

BARLEY

We have large Overseas Representation, and are in constant touch with the World's Markets, and strongly advise Growers, before selling elsewhere, to submit samples to us for valuation.

Delivery taken at any Railway Station, Siding, or Shipping Port.

F. W. HANCOCK & CO.,

CRANBROOK CHAMBERS, BENTHAM STREET, ADELAIDE.

TELEPHONE: CENTRAL 4855 and 4856.

Sheep.—At present we carry about 7 million sheep, but with the drainage of the South-East, improvements in pastures and feeding, storage and reticulation of water, and closer subdivision of holdings, this number should be doubled in the immediate future. Not only will numbers be increased, but the wool yield will be improved and the production of fat lambs will tend to better financial returns.

Pigs.—About 140,000 pigs are slaughtered annually for home consumption, and a few thousands for export, but if there is to be a great increase in the number of these animals maintained in the State it will be because of the development of an extensive export trade in pig products. These animals are reared so easily in the country, and barley and other grains are grown so readily, that it seems inevitable that in the near future South Australia will become an important exporter of pigs, and then enormous numbers will be reared in the country.

Dairying.—There are now about 130,000 dairy cows in the State, and when the South-East is drained and more of the Adelaide Hills cleared of scrub this number will be greatly augmented.

Poultry.—The great bulk of the 2,200,000 head of poultry are fowls, and because of the success being attained in the export of eggs it can be confidently expected that the marked increase in production which has taken place in recent years will be maintained, and that poultry will become one of our valuable lines of producers of an exportable primary product.

HOW TO BRING ABOUT THE INCREASED PRODUCTION.

The potentialities of the State are very largely dependent upon developing the South-East from an agricultural point of view. The possibilities of increasing production are enormous, as can be realised when it is remembered that there are about 1,000,000 acres of excessively wet land to be drained. At the present time there are about 3,500 effective holdings in the whole of the South-East, which on the average figure for the State will support about 59,000 people, of whom 25,000 live in the South-East. When the district is reclaimed it should mean at least 12,000 effective holdings, which will support about 200,000 persons.

With the reclamation of the wet land of the South-East the most marked increase will, in all probability, be seen with sheep, the flocks of which will contain millions more than at present. Not only will the numbers be increased, but a much higher proportion of fat lambs will be produced than is now the case. Although dairying is an important agricultural activity it will become increasingly so, and because of the luxuriance of the pastures the raising of baby beef is likely to be undertaken on a fairly extensive scale. The increase in dairying and the ease with which heavy crops of barley are grown will lead to multiplying several times over the number of pigs now maintained.

These big improvements can only be brought about by the expenditure of a good deal of money, because the thorough drainage of a large area of land, and the provisions of better transport facilities, are involved.

In other districts of the State the most advancement will probably be with cereal crops, sheep and vines as the principal ones, although there is fair promise of the pig population being increased enormously, and dairying must make some marked progress. The provision of water will have noticeable beneficial effects in the cereal-growing districts, particularly as regards the production from sheep, and the further clearing of good land in the Adelaide Hills will lead to more dairying being practised.

As agricultural advancement is only possible by increasing rural products that can be exported, it is imperative that any forward move in production must be accompanied by an improvement in quality, so an important factor in our progress will be agricultural education of a nature tending to keep country people up to date in methods of production and alive to market requirements. With perishable products to be used for human food strict legislation is required to ensure the articles opening up in good order on the other side of the world after some weeks in cold store.

ACTIVITIES AT ROSEWORTHY AGRICULTURAL COLLEGE, 1933-34.

PART II.—CULTURAL OPERATIONS AND GENERAL HARVEST RETURNS.

[By ALLAN R. CALLAGHAN, D.Phil., B.Sc., (Oxon.); B.Sc.Agr. (Syd.), (Principal), and O. BOWDEN, R.D.A. (Farm Superintendent).]

The total harvest returns, together with the livestock carried for the year, have already been given, and they summate one of the most successful agricultural years in the College history, both as regards "total yields" and "yields per acre." They are the more commendable when it is considered that finishing conditions in October were sharp and severe, with hot drying winds which took a very heavy toll of the thickest crops and reduced yields considerably. It is admitted that seeding and establishment conditions were ideal and no better rainfall distribution could have been desired, consequently all the fallow crops, except one or two which suffered in competition with soursobs, were well and evenly established, maintained excellent colour and growth throughout the growing period, and gave promise of especially good yields, but the season finished severely, and early hopes were greatly modified by the dry hot winds in October.

THE SEASON AND ITS INFLUENCES.

Prior to the commencement of seeding in April all fallowed land was kept in good condition by frequent cultivations, which were made possible and necessary by useful falls during the summer. With an early start of 94 points of rain early in March, stubble land intended for peas, oats, and barley was broken up, the rigid tyne cultivator and skim plough being commissioned to do the work. This early start in the preparation for stubble crops was reflected later in the general health and vigour of the crops, for there can be no doubt that the longer the period of preparation for oats and barley especially, the more nitrogen there is available and the better the colour, growth, and vigour of the crop. The rains in March also caused a good germination of weeds on the fallows and a very valuable cultivation was carried out.

In April, although the rainfall of 1.29 inches was slightly below the average for this month, most of the rain fell during four consecutive days and was very useful. A heavy thunderstorm this month had a splendid consolidating influence on the fallows. Extensive germination of weeds and the vigorous appearance of soursob followed the April rains, thus enhancing the value of fallow cultivations prior to seeding. During the latter end of April and in May ideal conditions for seeding prevailed. Rainfall in May was high at 2.99 inches, and well above the mean of 1.99 inches, but the distribution of the falls was particularly favourable, as good dry conditions for seeding separated three substantial falls. Fine mild conditions prevailed in June which encouraged rapid growth of all the sown crops, and enabled the remainder of the seeding to be carried out without any serious interruptions, and under ideal conditions. Only 74 points were registered in June, the lowest recording since 1914, and considerably below the mean of 2.74 inches for this month, but there was ample soil moisture to encourage steady growth.

From the seasonal notes so far recorded it is evident that seeding conditions were very favourable, and had the rain and weather been ordered, a better and more convenient distribution of rain and fine mild weather could hardly have been

obtained. Following this excellent start, satisfactory rain fell to the extent of 1.84 inches in July and good growth was maintained. Satisfactory precipitations were recorded in both August and September, and all crops promised well. Up till this stage growth had been rather too rapid and crops were very sappy, with an inclination to produce more straw than desirable. Looking back on the season now, it is apparent that this condition of the crops largely aided and abetted the harsh weather of October in taking such serious toll of yields. The rainfall for October was almost an inch below the mean, the recording being 67 points in comparison with the mean for October of 1.66 inches. In addition to the low rainfall the month was hot, especially the last fortnight, when, as though abnormally high temperatures were not enough, particularly dry and trying winds blew from the North. The extreme suddenness of the appearance of summer conditions had a marked influence on the crops, and final yields were considerably below early expectations.

November came around and the harvest was soon in full swing, the season had snapped off, and crops were compelled to finish and fill as much grain as well as possible, under adverse conditions.

The total rainfall recorded for the year was 16.85 inches, which was 0.67 inches below the average, and for the period April to November, defined in these reports as "useful" rainfall, there was a deficiency of 1.55 inches in comparison with the average. As the shortage was during the finishing phases of crop growth during flowering, development of the grain and maturation of the grain, the fact that yields were so high indicates that record crops might well have been harvested with even more average conditions in October.

It is the practice to compute the rainfall for the period April-November inclusive, and call it "Useful Rain," and while this is probably fair and logical for the later districts of the State, the period April-October in many districts similar to that in which the College is situated fulfils the purpose better, for November rains as a rule are too late to be of any use to the crop. This was certainly so last year, as the harvest was well under way before the end of November. For this reason, in comparing the harvest results from wheat for last year with the only other two years in which the average yield for all farm areas was greater than that of last year, the seasonal rainfall as defined by the period April-October is used. Further, this computes the data along the lines generally accepted in such work. The year 1929 is also included in the table, to show that although the actual yields were low, they were high in proportion to the amount of rainfall received during the growing period. The bushel yield obtained per inch of seasonal rainfall last year was a record for the College.

Comparison of Average Yield of Wheat with Seasonal Rainfall for Previous Good Years.

Year.	Total Rainfall.	April-Oct. Rainfall.	Average Yield Per Acre.		Yield Per Inch of Seasonal Rainfall.	
			Bush.	lbs.	Bush.	lbs.
1909	24.05	19.07	25	5	1	19
1920	19.30	14.88	26	57	1	49
1929	13.08	8.24	15	11	1	51
1933	16.85	12.61	24	51	1	58

For the sake of general comparisons with other State data, the following general information on the relationship between rainfall and yields obtained is recorded, and here the "Useful" rainfall, April-November, is of necessity used. Situated in the Central district of the State, it will be seen that the College returns are very much above the average for the district in yields of all cereal grain.

WHEAT.

Soil Preparation.—All wheat was sown on fallowed land, which had received careful and attentive preparation. The initial ploughing had been difficult because of the wet winter of 1932 and excessive growth of grass on the fields. Late Spring and early summer rains, however, apart from helping in the consolidation of underlayers, encouraged the germination of weeds and enabled two light workings of the fallows with spring tyne implements to be carried out during the summer subsequent to the harrowing down and first cultivation with the rigid tyne. The good rains in March and April of last year were of great help in the final preparation of fallows, and again light cultivations destroyed innumerable weeds and maintained good tilth. On the average the fallows, therefore, received five cultivations prior to a final cultivation before seeding. From this the operations concerned in the soil preparation may be summarised as follows as being representative of average fallow treatment for the year concerned:—

July, 1932—Ploughed to a depth of 3in.

August, 1932—Harrowed down.

September, 1932—Rigid tyne cultivation.

November-December, 1932—Some paddocks spring tyned, others harrowed.

January, 1933—All paddocks again lightly worked with either spring tyne implements or the harrows.

March, 1933—Some paddocks given cultivation with the rigid tynes, others covered with spring tyne implements.

April, 1933—Some paddocks given rigid tyne cultivation, others spring tyned. Seeding commenced on April 20th.

May, 1933—Final pre-seeding cultivations, seeding of paddocks.

June, 1933—Wheat seeding finished on June 10th.

The treatment outlined above undoubtedly called for a lot of work, and the number of times the fallows were covered is rather above the normal requirement, but the nature of the season was such as to make the treatments given quite necessary. Working of the paddocks was carried out soon after actual germination of the weeds and while the soil was in good moist workable condition. In this respect the season made fallow preparation easy and enabled all operations to be carried out under very favourable conditions for the preservation of good soil tilth.

The general result was that the fallows were in excellent heart for the reception of the seed. In one paddock a heavy sward of barley grass had been turned under when ploughed, and ploughing was rather later than normal. As the barley grass had been known to be diseased with Take-all, the precaution was taken to avoid the usual practice of sowing wheat. Consequently this fallow was sown to oats, contrary to usual farm practice. This paddock is marked "Graingers C," and shown in Map 1 (in June issue) to have been sown to oats on fallow in 1933, and as it is unusual procedure, the above explanation is given. Further, it indicates a useful point in management following the observation of Take-all on the barley grass, for the oat crop is rarely affected with Take-all, whereas wheat on this area may have suffered severely, besides carrying the fungus on over another season.

Seeding.—Wheat seeding began on the 22nd April and was completed on June 10th. Throughout, 1½ cwt. of Superphosphate were drilled with the seed. The College system of rotation whereby a paddock is rested as ley land once every three or four years warrants substantial dressings of superphosphate on the crop. The stubble feed the following year is always vigorous, trading as it does on the residual effect of the extra superphosphate added to the crop the previous year. Any farmer who is largely dependent upon stubble fields for livestock feed would be well advised not to spare the application of superphosphate on crop land intended to be rested the following year.

The rate of sowing, through the earlier portion of seeding, was 70 lbs., but for midseason sowing the rate was increased to 75 lbs., while the late seeding of early maturing varieties like King's White and Canberra was still further increased to 80 lbs. These seeding rates are high, but in the agricultural areas of the Central and Lower North districts, unless the fields are known to be free from weeds, competition is liable to be keen on lightly seeded areas. If it were not for the possibility of serious competition, lighter seeding may be possible and give better filled crops, but experiments carried out at College indicate that in most seasons the seeding of 70 lbs. per acre is the most profitable.

Following 70 points of rain in mid-April, the sowing of the field, "Crouchs C," with the variety Ford was begun. The greater portion of this field was known to be badly infested with soursobs, and as some other large fallow paddocks were also monopolised by this weed, it was realised early that sowing of all soursob areas could not be delayed pending the control of the weed. Consequently an effort was made to do the best under the circumstances, the paddock considered to be most badly infested, "Days C," was listed late on the seeding list, to be seeded after the soursobs had been checked by the cultivation, to an early maturing variety, but "Crouchs C" was sown early as soon as sufficient soil moisture was available to assure immediate and regular germination. For this paddock Ford was chosen as a reasonably long seasoned variety, possessing good vigorous growth habits. Germination was very rapid and satisfactory, the wheat grew rapidly, and at the outset gained a lead on the soursobs. This ascendancy was maintained throughout, and in spite of the blanket of soursobs which formed a dense undergrowth on the field, the wheat competed so successfully that the

soursobs, except for a few stray individuals, never flowered, and the wheat crop came through triumphantly with a yield of 26bush. per acre off 56 acres and nearly 3 tons of hay over the remainder.

It is interesting at this stage to compare the treatments and results from two other fields where soursobs were prevalent. "Days C" was sown late, finishing on June 10th, to Waratah. Additional to the treatment given to "Crouchs C" this field was cultivated, spring-tynd, and again cultivated, with the gratifying result that the soursobs were absolutely subdued, and after the wheat had braided, only a few weak soursobs were evident in the field, and their effect upon the resultant crop was negligible. From this field a yield of 26½bush. per acre was harvested off about 80 acres. Another paddock, "Dalys C," received intermediate treatment to those already cited, and was sown mid-season. This paddock was worked in April, at the same time as "Crouchs C" was being sown, but was subsequently cultivated and spring-tynd just prior to seeding on May 17th, to Ford wheat. Here both soursobs and wheat came away simultaneously, and with weather conditions more conducive to soursob growth than to wheat growth, the balance of competition was for some time largely in favour of the soursobs. The crop was thinned out considerably, the yield as a result was considerably lower, at 20½bush. per acre, than those obtained as a result of the paddock treatments previously described. One interesting feature worth noting here in connection with "Dalys C," is that at one stage in July the crop appeared to be beaten by the soursobs, and realising little harm could be done, the area was rib-rolled, and followed by the harrows. The tender soursobs were crushed considerably, yet the wheat suffered no ill-effects, and with opportune frosts following immediately, the soursobs yellowed slightly, lost their ascendancy momentarily, and the wheat plants were given a very needful advantage, with the result that they maintained competition on much more favourable terms than previously.

Without generalising unduly, it seems that to control soursobs early sowing of a vigorous variety, or the late sowing of an early maturing variety, after repeated cultivations, are far more preferable treatments to mid-season seeding. This latter is dangerous, and the most efficacious is undoubtedly to sow late after repeated cultivations, whenever this is possible.

Harvest.—Binders were rushed into commission at the end of October following the sudden appearance of hot dry weather, and by the close of the month, headlands, divisions, and portions of several fields, amounting to about 100 acres, had been cut, representing about 200 tons of hay.

The weather in November was dry and very satisfactory from the point of view of harvest; only 29 points of rain were recorded. Hay-cutting proceeded uninterruptedly, and by the end of November over 300 tons had been carted and stacked. On the 20th November the first wheat was harvested, and by the end of the month both "Crouchs C" and "Dalys A" were completed and the paddocks cleared for stock. Additional to hay and general harvest, some experimental areas were cut with the binder to be threshed for grain with the large threshing machine; this involved a good deal of extra labour. From the threshing a stack of approximately 100 tons of splendid baled straw was obtained. Hay-carting was completed just prior to Christmas concurrently with other harvest operations. Considering the quantity of produce handled the performance reflected great credit on the students, all of whom displayed great enthusiasm and willingness.

The yields obtained from the various fields and individual varieties are given in the following tables. The tables are kept apart so as to distinguish between those sown to large areas from those of small acreage, otherwise they would

be of less value. In fact, it is wrong to assess comparative varietal values from these tables at all, as so many other factors enter into the matter, such as differences in soil, soil preparation, and time of sowing, but they do serve some service in that they indicate the general suitability or otherwise of the particular variety for the district.

Wheat Yields from Farm Areas.

(a) Varieties of which at least 10 Acres were Harvested for Grain.

Variety.	Field.	Area in Acres.	Yield Per Acre.	
			Bush.	lbs.
Sword	Dalys A	43	26	35
Waratah	Days C	80	26	29
Ford	Crouchs C.	56	26	0
Nabawa	Nottles A.	50	25	53
Sultan	Ebsarys	13	23	18
Late Gluyas	No. 3A.	21	21	26
Ford	Dalys C.	40	20	47
Free Gallipoli	Graingers A2	27	15	46

(b) Varieties of which less than 10 Acres were Harvested for Grain.

Ranee 4H.	No. 9	3 $\frac{1}{4}$	35	25
Ranee 4H.	No. 4A.	$\frac{1}{4}$	32	33
Baringa	No. 9	$\frac{1}{4}$	31	47
Dundee	No. 9	$\frac{1}{2}$	27	23
Dan	No. 3A.	$\frac{1}{2}$	27	18
King's White	Ebsarys	5	20	33
Canberra	Ebsarys	3 $\frac{1}{2}$	17	20
Felix	Ebsarys	3	14	44

The varieties sown to large areas are all fairly well known, but some sown to smaller areas are comparatively new. Two separate results given for Ranee 4H indicate that this variety might have a big future under our conditions. The good quality wheat Dundee, from New South Wales, acquitted itself very well. Baringa also gave good returns. This latter is a wheat unlikely to become very popular because of difficulty in stripping; it holds its grain tenaciously except under ideal harvesting conditions. Dundee is a bold-headed variety with distinct possibilities, especially as its grain quality is superior to any varieties now grown to any extent in South Australia.

Until these varieties are given a proper comparative trial with such consistent varieties as Sword and Ford, it would be both unfair and misleading to accept the yields stated as truly indicative of their capacity. Certainly Ranee 4H and Dundee are worth close watching; both will be in the variety trials this year. Of the better known varieties, Sword and Ford undoubtedly suit the lighter soils of the Central and Lower North. They both enhanced their reputations last season, chiefly through their capacity to fill well in spite of bad finishing conditions. The Nabawa in a similar state of maturity to Sword and Ford, when adverse weather set in, suffered far more severely, yielding less and a much less-plump sample of grain. Waratah finished very well, but it was just late enough at heading, because of late seeding, to miss the critical October weather, and it had the benefit of milder less-dry conditions for finishing. There is no doubt, however, that Waratah is a useful variety for late seeding. Of the others, Free Gallipoli was most disappointing, and under low rainfall and shorter seasonal conditions it does not fulfil the promise its early growth gives. Given cooler and moister spring conditions, it yields well, but the environment at College certainly does not suit it. This year only a pure seed area of Free Gallipoli is to be sown.

Wheat Diseases.—The crops were remarkable for their freedom from disease, no serious toll being taken of any of the crops. The season was such that a rust epidemic would have been impossible, as no more unsuitable circumstances could have been possible. Curiously enough, the erstwhile innocuous leaf blight (*Septoria*) was perhaps the worst disease of the year; it was particularly severe on Free Gallipoli, and probably was instrumental in reducing the yield of this variety. Flag smut was not much in evidence, though in one paddock of Ford there was a slight sprinkling of infected plants. Loose smut was noted to a slight extent in Sultan and King's White. As far as is known Take-all and Bunt were entirely absent.

HAY HARVEST.

A total of 140 acres of cereals was harvested for hay; this was made up from 106 acres of wheat and 34 acres of oats. The average yield per acre obtained from the sown areas was 2 tons 4cwts. 19lbs., which is 5cwts. 23lbs. above the mean yield. This average return is high when it is considered that a large quantity of the hay was taken from headlands and divisions. About 40 acres of self-sown material, chiefly Burr medic and cereal, were harvested in "Days A" and "B," a stack of approximately 50 tons of good quality meadow hay being obtained, at an estimated yield of 1 ton 5cwts. per acre.

The cereal hay was of fairly good quality and retained its colour well, but all crops were rather light for the bulk harvested. Some very satisfactory yields were obtained in spite of this, and that of 2 tons 18cwts. from 30 acres of Ford was the most outstanding. Even in this case the crop was bulky enough to give a higher yield had normal weight been present. The rapidity of growth throughout the growing period and general sappiness of the crops when the dry hot weather of October literally scorched them, probably accounts very largely for the comparative lightness of the sheaves.

Hay Yields, 1933.

(a) Wheaten Hay.

---------------------------------	---------------------	----	---	---	---

Stubble Crops.—Except for one paddock, all oats, barley, and pease were sown to stubble fields, the exception, as already mentioned, being a fallowed area where barley grass affected with Take-all had flourished prior to initial ploughing; this was sown to oats. In all cases the early opening rains enabled the skim plough and cultivators to do good work much earlier than usual, and there

can be no doubt that it pays to begin the working of stubble fields early for the best results. The opening up of the soil, together with the destruction of grass and weeds, enables active nitrification to proceed in the soil while the warmth of Autumn is still available. The initial breaking up of the soil, be it done with plough, skim plough, or cultivator, must be shallow for stubble crops, and nowhere were the paddocks worked to a greater depth than 2in.

Oats.—All oats were sown as early as possible, with the idea of checking excessive growth by feeding off during the winter. This practice is very sound on clean land, and in districts where early working of stubble land is possible, for oats stand feeding off better than any other cereal, as they have greater recovery power. Once they are well rooted practically all varieties of oats can be grazed extensively and still give crop returns where the season is long enough. In the case of the College paddocks last year, No. 15 was sown in April to Early Kherson, and all oat seedings were finished early in May. All varieties were sown at the rate of 50lbs. per acre with 1cwt. of Superphosphate per acre. After a quick establishment they made excellent early growth, and were fed off to the ground during June, after which they were rolled and allowed to grow unchecked for the remainder of the season.

Under the above treatment it is not surprising that the crop in "Grainger's", sown on fallow, eventually proved far superior to that in No. 15. Taking into account the heavy grazings given, and the bad finishing weather, the average yield of 29bush. 35lbs. from 83 acres, including experimental areas, was satisfactory, exceeding the mean yield for the past 28 seasons by 6bush. 14lbs., and being very much above district and State averages as shown in an earlier table.

The following are the results from farm areas:—

Oat Yields from Farm Areas.

Variety.	Field.	Area in Acres.	Yield Per Acre.	
			Bush.	lbs.
Early Kherson	Graingers C.	6	50	36
Algerian	Graingers C.	4	49	33
Sunrise	Graingers C.	7	41	38
New Zealand Cape	Graingers C.	5	32	3
Guyra	Graingers C.	1	24	29
Early Burt	Graingers C.	1	24	25
Early Kherson	No. 15	29	17	22
Lachlan	Graingers C.	3	15	21

The results from Early Kherson and Algerian in comparison with other varieties grown in the same field bear out the opinions held with regard to the general usefulness of these two varieties. Of the early maturing varieties at present in cultivation no oat gives such satisfactory yields of either grain or hay, following winter grazing, as does Early Kherson. It is of vigorous, free-stooling habit, producing an abundance of early feed, yet after grazing, recovers wonderfully well and proceeds to grow as though it had not been checked. For this reason Early Kherson can be recommended as an oat capable of giving an abundance of green feed and standing plenty of grazing. Algerian also has wonderful powers of recovery, but, being a late maturing variety, it has not the early vigour of Early Kherson, consequently it does not produce the same bulk of early feed. For this reason it is not so valuable as a grazing oat. Under the same field conditions it is interesting to note the very poor yield from Lachlan, but this variety has not the same recovery powers possessed by the other oats

represented; a certain recovery after grazing does take place, but the plants never seem to recover the full vigour necessary to produce sufficient panicles of well-filled grain in comparison with a variety like Early Kherson.

Reverting again to Early Kherson, a word on its grain characters should not be out of place. The grain is very small, and many farmers are prejudiced against small-grained oats. This may or may not be a real objection. Certainly Early Kherson is a fairly thin-hulled oat and is therefore of good feeding value, although its size may lead one to suppose that it has not the feeding value of plump oats such as Lachlan or Guyra. Farmers growing Early Kherson for the first time might well bear this in mind, and not let their early prejudice condemn a perfectly good oat variety because it has small grain.

Barley.—The season was not a particularly favourable one for barley culture. Mild moist conditions during the winter and early spring encouraged rather too luxuriant growth. The presence of barley mildew, which was quite bad in places, was indicative of the heavy, dense sappy nature of the crops. All barley progressed well until heading time, and gave excellent promise; indeed, areas of barley cut for ensilage gave phenomenal returns of especially sappy green fodder. Unfortunately, the October weather, which has entered very largely already into the story of this report, had a most exacting influence, and the barley was so severely checked by the abnormal weather that it never really recovered to any great extent. Plants which were heading at the time were so badly affected that they set no grain, and on examination of many plants the flag was quite brittle, breaking into chaff on pressure, yet the normal green foliage colour was retained. The general result was that all barley harvested was badly pinched, and yields were very low and disappointing in comparison with the stands and denseness of crops.

Blood Manure

Bone Manure

The farm area under barley was small, the greatest area being included in experiments. In the experimental plots the results of which will be itemised in another report, some of the barley, especially that with heavy dressings of Sulphate of Ammonia, was exceedingly poor. These experimental plots enter into the general average yield, given in the first of these reports as 21bush. 42lbs. from 38 acres; this figure is below the mean yield for barley over the last 28 seasons at College, by 2bush. 34lbs., yet it is substantially above average district yields and average State yield for the year as shown in an earlier table. The rate of seeding for all barley sown on the farm was 1½bush. per acre with lewt. of Superphosphate.

The following shows the yields from the main farm areas. The table includes only about one-third of the area devoted to barley, from which the average is assessed, the remainder being experimental.

Barley Yields from Farm Areas.

Variety.	Field.	Area in Acres.	Yield Per Acre.	
			Bush.	lbs.
Prior	No. 5A.	6½	26	21
Tunisian.....	Plot L.	¾	25	26
Roseworthy Oregon ...	No. 5A.	1½	25	32
Californian.....	Plot E.F.	1½	22	9
Shorthed	No. 5A.	1	20	20

Of the varieties Tunisian is quite new, being imported from Northern Africa. It is a vigorous-growing variety of the feed type and should be useful as a grazing barley, or for ensilage, or as grain for feeding purposes. The grain is too bluish, harsh, and hard to be of value as a malting sample, or, at least, such were the indications on the sample harvested last season. Californian is also comparatively new, but as the grain was badly pinched as a result of the adverse seasonal conditions, it was useless for malting, consequently it is impossible to express any opinions in this connection. It is a vigorous barley, however, and may be quite useful as a general purpose variety on the farm.

Pease.—This crop was not grown to any extent at the College last year, partly because of the shortage of seed, and partly because the general rotational policy of the paddocks had not been finally laid down. Their value in a rotation is not as widely appreciated as might be, especially as very payable returns can be obtained either direct or for feeding on the field or farm. Probably the chief limiting factors to their more general acceptance has been the ravages of grubs in the past, coupled with the fact that late maturing varieties were chiefly used. The more general use of the early maturing White Brunswick variety has led to far more satisfactory results. Certainly the grubs have not been as troublesome in the last few years as formerly. Apart altogether from direct returns, the fact that pease are grown to maturity on the land, and the haulms fed off to stock, has a very appreciable influence for good on the soil, increasing both supplies of nitrogen and organic matter. All pease were sown on stubble land after normal preparation at the rate of 2bush. per acre with 1½cwt. of superphosphate, with the combine.

The small area of 38 acres sown to pease at the College last year gave an average yield of 15bush. 50lbs., which included 16 acres of experimental pease. From the 22 acres sown under normal conditions, however, a yield of 20bush. 53lbs. was

recorded. This year a larger area of pease has been sown, and they will be used in the rotation more extensively in future.

Ensilage (Cropped).—Approximately 70 acres of stubble land, including about 40 acres of an old experimental field hitherto known as the Fence Plots (now discontinued) were prepared with the skim plough and sown early in April to oats (Early Burt) and barley (Roseworthy Oregon) for ensilage. These made extraordinary growth, benefiting from the late Autumn and early Winter rains while growing conditions were ideal. For any other purpose than for ensilage the crop would have been far too rank and tall to finish; as it was, some lodging took place before the binders were put in about mid-September. The fodder was in wonderfully succulent condition for ensilage and that maximum bulk was obtained is borne out by the yields. Both oats and barley were harvested together and ensiled load for load; the main yields were not kept separate, but from the field an average return of 7 tons per acre of green fodder for ensiling was harvested, and from two strips of barley the astounding return of 9½ tons per acre was recorded.

Of the sown cereal harvested for ensilage, 270 tons were chaffed into the overhead silos, and the remainder was stacked in two stacks in the field: one a pole-guided stack, the other an ordinary round stack. The total of sheaved fodder harvested for this purpose was 490 tons, which, together with 240 tons of self-sown fodder ensiled as stack ensilage, brings a total of 730 tons for the year, which easily constitutes a record for the College. Reference to the advisability of taking full advantage of years of plenty has already been referred to in the opening comments to these reports, while full details of the ensilage-making at the College last year are in course of preparation and will receive separate notice later on.

Ensilage (Self-sown).—As already stated, 240 tons of self-sown fodder were stacked during the year. All of this was taken from the field "Days A and B," which in the previous year had been cropped to wheat. With the opening rains in April this paddock was closed to all livestock. A veritable carpet of Burr medic (*Medicago denticulata*) quickly established itself, together with a moderate sprinkling of self-sown cereal and some barley grass. This growth traded on the wonderful growth conditions which prevailed during the Winter, and there can be little doubt that the ultimate luxuriance of the fodder present was due to this, but made possible from the residual effects of superphosphate. The practice of using liberal dressing of superphosphate with wheat that is sown to fields intended to rest the following year as ley or pasture land is undoubtedly sound, and returns in livestock carrying capacity will in normal seasons undoubtedly cover the cost of any extra superphosphate used on the crop, even though direct returns to warrant its use may not be obtained from the crop itself.

By the end of August the field was knee-deep in fodder, and it was decided to cut as much of it as possible for ensilage. A start was made the first week in September, using a mower to which was attached a number of iron rods which delivered the sward in a roll. The fodder was collected from these self-rolled wind rows with sweep-rakes and drawn to the site of the stack. It was then tipped from the rakes, and hauled on to the stack with a grab stacker. This method of handling the loose fodder greatly minimised the work and was economical of labour, time, and energy. Two round stacks, one of 130 tons, the other 110 tons, were built in this fashion from an area of approximately 80 acres. The remainder of the fodder in the field was converted into meadow hay or fed off.

This field attracted great attention throughout the year, and it stands as a striking example of what can be done by the liberal use of Superphosphate.

THE BAKING QUALITY OF AUSTRALIAN WHEATS.

No. 3.—BREEDING WHEATS OF BETTER BAKING QUALITY.

[By E. J. BREAKWELL, B.Sc.Agr. (Syd.), Plant Breeder, Agricultural College, Roseworthy.]

[The urgent need in Australia for wheats of better baking quality has been stressed and the work in cereal chemistry being conducted at the College described in articles published in the last two Journals of the Department of Agriculture. It now remains to outline the applicability of the latter in assisting to attain the former objective and to describe the possibilities of hybridization and selection as means of improving the quality standards of Australian wheats.]

Until recent years, to those pioneer plant breeders who realised the necessity of breeding wheats of good baking quality, the task of selecting with that objective was enormous. Apart from the primitive biting test, there was no simple method by which baking quality could be determined. It was necessary to continue all promising lines until sufficient grain for a baking test was available. Such procedure was both laborious and wasteful, the facilities made the possibilities of success remote, and it is not surprising that opinions expressed the improbability of combining baking quality with yielding ability in varieties bred for Australian conditions. The obvious defect in the earlier methods was the paucity of the number of crossbred lines. Since a large amount of grain is required for a baking test, it was possible to handle only a relatively very limited crossbred population. In addition, it was impracticable to test any large number of lines by baking and therefore the chances of isolating a strain possessing the desirable combination of yield and quality were extremely remote. There is no doubt that this association is not common, but the production of high yielding wheats possessing good quality at least is not impossible; this is shown by such wheats as Dundee, Ford, Canimbla and others.

The plant breeder has been awaiting a test by which he might select for quality in the early generations. Such a test must be both rapid and easy in operation, yet it is not imperative that it should reveal the detailed characteristics of samples from the point of view of quality. It is sufficient for the purpose if it distinguishes accurately between wheats of good, bad and indifferent baking quality. Such, it is claimed, is done by the Pelshenke Test, and by using this test, the plant-breeder is able to classify a large number of early generation crossbred lines into the different groups for quality; such classification would be impossible without it.

HYBRIDIZATION.

The chief method at the disposal of the plant-breeder in breeding wheats for high quality has been that of hybridization. A cross is made between two varieties—usually one possessing high quality and the other of indifferent quality but with good yielding ability. Selection is commenced in the second generation or F₂, and broadly, the aim of the plant-breeder is to isolate a particular type combining the high yielding ability of the one parent and the quality of the other.

Flintiness of the grain and the biting test have, in the past, been the only guides to quality, and these are unsatisfactory; in fact, they may be misleading, engendering false hope. Under such circumstances it was not until the fourth or fifth generation, when sufficient grain became available, that the strain could be tested by means of the baking test.

With the advent of the Pelshenke test, the method can be modified considerably. The scheme to be pursued at the College in the future is one of "bulk" handling—the term "bulk" being used for want of a better. A large number of crosses have been made, and from these, in the second generation, single plant selections will be harvested in the usual manner, though more plants than is customary will be selected.

In the third year three rows will be sown with the grain from each plant and before harvest a number of single plant selections taken from each F₃ line. Part of each line will be cut in bulk and the grain tested for quality by the Pelshenke test. If the figure obtained for a particular strain is satisfactory, then the plants with good grain character selected from that line will be retained and all others rejected. Likewise all single plants selected from lines of inferior quality will be rejected. The chances are that a single plant selection taken from a high quality line will be of good quality itself. To make sure of this, the fourth generation will be treated in exactly the same way, so that in the fifth year, from the large number of selections in the F₂, only those lines possessing satisfactory quality will be retained, and in most cases the factors governing quality should be approaching stability, thereby exhibiting a minimum of variability; in other words, they should be almost fixed for quality. If it is considered necessary, further tests may be used at this stage to verify the quality of the lines.

Yield testing on a small scale will be carried out from the fourth generation onwards, and by the frequent use of checks in the breeding plots, an indication at least of the potential yield of the different lines will be obtained and all those palpably inferior to the standard varieties rejected.

The method can only be successful when large number of lines are handled, otherwise that rare combination of quality and yield would probably escape detection as it has very likely done in the past, when less accurate methods of isolating good quality types were all that were available.

TESTING CROSSBREDS FOR QUALITY.

For the preliminary examination for quality the Pelshenke test is the only one yet devised which is suitable, being rapid and economical in time and material. Between harvest and sowing it is possible to test as many lines as the plant-breeder is able to handle in his plots.

At the College this year, with the aid of student labour, as many as 60 lines were tested in duplicate by the Pelshenke method in a day. Instead of a thermostat, a large tub is used containing a perforated tray which will hold about 50 beakers. The tub is filled with water to about 2 in. above the tray and heated with bunsen burners. Testing is done in the summer months, and by virtue of the large body of water the temperature can be kept very even, and no difficulty was encountered in obtaining a constant test figure for the check samples. The actual technique employed has been described in a previous article and it would be mere repetition to give a further description here.

A few figures are tabulated on next page to illustrate the range in quality which might be expected in a crossbred population. These have been obtained from material already in advanced generations, but which has not been previously selected for quality.

Ford x Carrabin. Fifth Generation.

Line.	Test Figure.	Grain Sample.
1	85	Excellent ; hard, plump, flinty.
2	107	Good ; plump, large, hard.
3	52	Very good but softer.
4	53	Poor ; rejected.
5	45	Soft ; rejected.
6	54	Plump but not hard.
7	51	Poor ; rejected.
8	46	Resembles Ford ; softer ; rejected.
9	57	Plump but not hard.

The test figures for Ford and Carrabin are 65 and 120 respectively.

Nabawa x Canberra. Fourth Generation.

Line.	Test Figure.	Grain Sample.
1	52	Hard but shrivelled ; rather poor ; rejected.
2	60	Good, hard, fairly plump.
3	73	Large, hard, slightly shrivelled.
4	77	Very good, large, hard, rather narrow.
5	52	Very fair, softer.
6	43	Shrivelled ; rejected.

The test figures for Nabawa and Canberra are 45 and 55 respectively.

From a scrutiny of the results it appears quite reasonable to anticipate the evolution of crossbred lines which are either higher or lower than the limits defined by either parent. This is probably due to complementary factors possessed by the parents—a combination of these factors which did not find expression in the parents, results in a line the quality of which may be higher or lower than that of the "high" or "low" parent.

It will be seen from these two examples that there is some association between the hardness of the grain sample and the test figure, but on this year's observations at least, this association was too often absent to be of much practical importance in gauging quality. For example, Line 2 in the cross Nabawa x Canberra appeared harder than Line 1 in the cross Ford x Carrabin, yet the latter obviously has the better quality. This bears out the experience of others.

THE POSSIBILITY OF SELECTING FOR QUALITY WITHIN A VARIETY.

Within the last few years there have been many complaints from leading farmers in South Australia that the supposedly "pure" varieties are showing variation.

Varieties such as Ford, Sword and Nabawa have been criticized from this standpoint. Sword is said to contain at least three types—the purple-strawed, the pinched-grained and the plump or true Sword. Ford has shown a marked range in glume colour, awn length and disease reaction. Plants within a "pure-seed" crop of Nabawa have been noted to vary in height and maturity. Under South Australian conditions at least, it would appear that these and other varieties are not entirely without variation; indeed, they give the impression that they are not fixed in the usual sense of the word or were not truly fixed before they were released for general cultivation.

Morphological variations, such as occur in Sword and Ford, are obvious to the naked eye, and a feature of the pure seed work to be conducted at Roseworthy College will be the selection of the more desirable types from the variable varieties

in an endeavour to fix a superior strain. The purple-strawed type, which often breaks off at the head, and the pinch-grained type, obviously, have a deleterious effect upon a crop of commercial Sword. An effort will be made to fix the true type of Sword. The same applies to Ford, Nabawa, Bencubbin and others.

The conception of a variety as an agricultural unit is such that variability might be expected from even visible characters but not to the extent noticed in crops of Ford, Sword and Nabawa. In fact, the interpretation of a variety, as it is commonly known, is involved, and the following quotation taken from an article written by Dr. A. R. Callaghan for August, 1932, puts the matter in succinct form:—"Technically speaking, a variety should be a pure line, but from a practical viewpoint, provided the plants representing a variety are sufficiently homogeneous to constitute a group which has inherent morphological and physiological characters which make it distinct from any other such group, minor inherent differences between the plants within the variety are permissible." Morphological characters such as colour of glumes, grain character and height obviously vary in some of our South Australian varieties, and this being so, it is highly probable that physiological characters such as capacity for yield and disease resistance and those morphological characters of a qualitative nature, such as baking quality, must also vary. In other words, if variation exists in characters which are visible to the naked eye, it is logical to suppose that it is also present in those which are not so easily discerned; for example, in baking quality.

To determine the extent of this variation, quality studies were made recently at the College on several well-known varieties.

MATERIAL.

It was realised that the selection of suitable varieties upon which to work would be an important factor in the ultimate results.

Sword, Ford, and Nabawa automatically suggest themselves as they show so much variation in other characters and are all extensively grown in the State. On the other hand, as contrasting varieties Gullen, Dundee and Baringa, all promising introductions from New South Wales, were chosen because they appear to be fixed in visible morphological characters, while Florence was taken as representing the older South Australian varieties.

Fifty consecutive single plants of Sword and Ford, a slightly greater number of Nabawa, and 12 consecutive plants of the other varieties, were harvested from the pure seed rows. A large population of Ford was also harvested, but this will be discussed under a separate heading. Plants were threshed in the single plant thresher and the Pelshenke Test was used to assess the baking quality of each single plant. Wherever possible tests were made in duplicate.

RESULTS.

The figures obtained in the tests need hardly be given in detail, but the summarised results are as follows:—

Baringa.—Range of 30 to 39 minutes; mean 35.

Gullen.—Range of 28 to 44 minutes; mean 37.

Both varieties show a limited range in the test figures of the single plants, which is typical of a pure line.

Dundee.—Range of 120 to 190 minutes; mean 165.

Florence.—Range of 55 to 129 minutes; mean 74.

Both Dundee and Florence exhibit considerable variation in the quality of the single plants. The range of Dundee may be insignificant, or, at least, less significant, as the selectivity of the test diminishes as the test figure becomes higher. The figures from Dundee are exceptionally high, probably due to the fact that the twelve plants of this variety were grown in the nursery plots—circumstances of growth which are known to enhance the quality of any variety.

Florence varies significantly, and one sample took 30 minutes longer than any other to break. Incidentally, this sample possessed all the characters of a strong wheat such as high passing power and stronger gluten as determined by the greater expansion of the ball and the longer time taken for disintegration. The variation occurring in this variety cannot be accounted for by experimental error or normal pure line variation.

Nabawa.—Fifty-five single plants of this variety were tested, and of these 53 ranged between 28 and 66 minutes, which might be expected of Nabawa, which has a test figure of 40. The other two samples gave test figures of 90 and 132 minutes (the latter being tested in duplicate), and in doing so exhibited all the characters of a strong wheat.

Sword.—Fifty single plants ranged from 32 to 72 minutes, with a mean of 46 minutes. The distribution was fairly even, though there was a marked tendency for the plants of low quality to predominate. Samples with a test figure of more than 50 minutes generally exhibited all the characters of a wheat of medium strength. It is unlikely that a variation of this magnitude would be shown by a pure line. The variation in the baking quality of single plants of *Sword* appears to be even greater than that exhibited by visible morphological characters, some of which are known to be very variable. It is also interesting to note that the lowest and highest figures for the single plants in this variety, viz., 32 and 72, are similar to the test figures given by the parents of *Sword*, namely, *Sultan* and *Ford* respectively.

Ford.—Fifty plants taken from a pure seed row ranged from 42 to 80 minutes, with a mean of 60. The distribution was remarkably even.

The Possibility of Selection.—The figures obtained lead one to consider the possibility of isolating the highest quality plants with the object of building them up into superior strains. A strain of *Sword* which gave a *Pelshenke* figure of 72 would be vastly different from one with a figure of only 32. If this high quality strain proved to be similar to *Sword* in all other characters and retained its high quality, it would be a first class wheat, not only from the growers' point of view, in which the criterion of value is the capacity for yield, but also from the point of view of the millers, from whom the variety has so far not attracted special notice.

The ultimate success of such an endeavour to isolate strains with superior quality and have them accepted by the farmer would depend upon two things:—

1. Whether the strain would be equal to the commercial variety in yielding ability.
2. Whether the high quality plant would breed true to type.

It has been admitted previously in this paper that high quality is not generally associated with high yield, but one is hopeful that some of the high quality plants of *Nabawa*, *Sword* and *Ford* will give rise to strains which will be equal in yield to the commercial strains. Moreover, with this method of selection for quality within a high yielding variety, it would appear that there is less danger of losing those characters determining yield than there is in selecting within a crossbred population the high quality parent of which is generally low yielding.

Even the elimination of the low quality strains should materially enhance the quality of the variety and should have very little effect upon yield. This method will be resorted to in the event of the high quality strains lacking yielding ability.

The question whether the high quality plants will breed true to type is probably of more importance. It has often been shown that a pure line, i.e., one which is true to type, cannot be altered by selection. Many minor variations which may be seen are known as fluctuating variations. An example is found in a study of the ear size in a crop. Large ears, intermediate-sized ears and small ears are common to every crop. The continuous selection of the large ears from a fixed variety from one generation to another will not produce a variety which will yield

all large ears, nor is it possible to raise the average size of the ears of a pure variety. Thus it may be argued that the plants which show high quality this year would next year produce progeny which tended towards the average quality of the variety. This would be true if the varieties under discussion were pure lines, but work done at the College has given evidence that Ford at least is rather a mixture of pure lines.

INVESTIGATIONS WITH A POPULATION OF FORD.

In 1932, single head selections were taken from a commercial crop of Ford. The seed from these heads was sown in adjoining rows in the hand plots in 1933. Each seed was space planted. The resultant lines, 41 in number, showed great variation in maturity, height, head characters, &c. Ten consecutive single plants were harvested from each line. All single plants of which there was sufficient grain were tested by the Pelshenke test. In all, 350 single plants from the 41 lines were tested.

Some representative results are given:—

Strain 1.	Plant No.	Time.	Strain 2.	Plant No.	Time.
	9	96		8	44
	4	98		5	49
	8	103		7	50

Mean 58			Mean 72		
Variation 5 9%			Variation 9 15%		

Discussion of Results.—A study of the strains of Ford tested shows that the variety is a mixture as regards quality and the outlook for isolating a high quality line is at least encouraging. It must be remembered that each strain

arises from a single head, selected at random from a normal crop of Ford, and the strains were grown in close proximity to each other and received exactly the same treatment.

Some strains show a considerable range in the quality of the single plants therein. The greatest range is 45 per cent. from the mean, or 34 to 72 minutes. However, 31 out of the 41 strains tested exhibit a range of 20 per cent. or less from the mean, and hence can be regarded as pure lines from the viewpoint of quality at least. The mean figure of the strains is very variable, ranging from 55 to 122 minutes. There are just as many high as low quality strains, which indicates that there is a large population of high quality plants from which to select. If the single heads had been obtained from a pure line in the original selection, the mean figure for the strains could not have been nearly so variable.

It appears reasonable to expect that if all the single plants were sown this year, they would produce strains showing the same variability as their parent strains did last year, after allowing, of course, due consideration for any seasonal variation. For example, Strain 3 varies between 97 and 114 minutes and appears to be fixed; so that any plant selected from it should this year produce progeny exhibiting the same range and the same mean. In other words, it should breed true to type.

The variation in the quality of the single plants of some strains is considerable. Strain 11 ranges from 88 to 143 minutes. It is difficult to account for the occurrence of variations of this magnitude within a strain, and this will not be attempted until additional data are obtained. At present, the most likely explanation appears to be that natural crossing has recently taken place between plants, the quality of which was inherently different. A study of the behaviour of these particular strains in succeeding generations will probably furnish an explanation of the phenomena.

The mean quality figure of a heterozygous crossbred population which was grown in bulk from year to year would not vary to any extent, but if a single plant selection was taken at random or irrespective of inherent quality, as is done in pure seed work, a strain of inferior quality might be produced. Consequently it is imperative to fix a strain for quality before it is even suggested for commercial culture.

In seeking to account for the fact that Baringa and Gullen are not nearly so variable as Ford and Sword, a comparative note on the lines of selection suggests itself.

In modern practice, pure seed production is conducted on the basis of single plant selection. A typical single plant is selected from the variety and the seed is increased from year to year and finally distributed to farmers. Previously, however, a common method has been to clip off a number of typical single heads from a variety and build up for distribution the seed thus obtained. The result is that minor variations, especially the less obvious, which were originally present in the variety, or which might occur naturally from year to year, are largely maintained. Ford and Sword have been evolved by the method of bulking single heads.

With single plant selection the variety, if it has any variation, soon becomes fixed, and this is probably the reason why the New South Wales varieties under review show little or no variability when compared with Sword and Ford, as the individual plants have been the unit of selection there since the time of Farrer.

The range of types existing in Nabawa and Florence is more difficult to explain. If these varieties were not fixed when the College obtained them, then the reason for their variability is the same as that for Sword and Ford. If they were fixed,

then the only explanation is that the method of bulking single heads has perpetuated any slight differences as well as any which may have arisen in the course of time. With single plant selection and subsequent isolation, the chances of perpetuating variations is negligible, for errors in original selection can be corrected in subsequent years when these are grown as separate lines side by side with the selections true to the type desired. The method of single plant selection as opposed to that of bulking a number of typical heads is the one now practised at Roseworthy College. Under such a system a superior strain of any variety once isolated can be perpetuated in its original form far more successfully than by any other method.

From the point of view of work being undertaken on quality, it is rather fortunate that the method employed at Roseworthy in the past has been that of bulking the single heads, for it has given rise to material which lends itself to selection for quality, a selection outside the orbit of past plant breeders, chiefly because there was no suitable test at their disposal.

By way of conclusion, it might be stated that although the foregoing is largely of arbitrary character, based more on inference than fact, there is sufficient evidence available to warrant an optimistic outlook with regard to the possibilities of selecting wheats of satisfactory baking quality from already existent varieties. Although time is required to test out the possibilities, the indications are present and are supported by scientific principles, that many of our varieties lend themselves to selection from the point of view of such abstruse characters as those which contribute to baking quality. It appears that those varieties which have received the least rigorous attention, especially in early selection, present the greatest possibilities for improvement along these lines, and it may prove to be a blessing in disguise that such well-known varieties as Ford and Sword should fall into this category.

THE IMPORTANT PASTURE PLANTS OF SOUTH AUSTRALIA, CONSIDERED AS TO THEIR INDENTIFICATION AND CHARACTERISTICS.

[By E. M. HUTTON, B.Ag.Sc., Field Officer.]

(Continued from page 1403.)

In the previous portion of this article the *Lolium* and *Phalaris* groups were discussed. As far as South Australia is concerned, *Phalaris tuberosa*, Perennial Rye Grass, and Wimmera Rye Grass are proving to be the outstanding grasses. The groups which are to follow are less important, and the grasses contained in them are either of doubtful value or are of value only under special circumstances.

III.—THE VELDT GRASSES OR EHRHARTAS.

The leaf blade has few hairs, and is produced into two small auricles which bear about a dozen long hairs. The emerging leaf shoot is rolled, and a medium-sized ligule is present. These grasses usually have a purplish colouration, which is either on the leaves or at the auricles.

The seed head is an open panicle, the spikelets being reddish or purplish in colour.

1. PERENNIAL VELDT GRASS (*Ehrharta calycina*).—It is distinguished by its perennial tufted habit, and by the fact that both the ligule and auricles are purple. (See Fig. 6.) The leaves often assume a deep red or purplish tint.

Fig. 6. Showing purple auricles and ligule of Perennial Veldt grass. Note also the long hairs on the auricles.

This grass will provide a bulk of soft succulent feed on the advent of autumn rains. It appears that it is not resistant to grazing.

It grows luxuriantly, and spreads rapidly by seed on poor sandy soils in the higher rainfall areas, e.g., Mount Compass. The grass also shows undoubted drought resistance, and thrives on the lighter soils of the cereal cultivation belt.

This grass has recently engaged the attention of research workers, and seed is procurable only from them.

2. ANNUAL VELDT GRASS (*Ehrhata longiflora*).—Is an erect growing annual, with broad bright green leaves, which show crinkled portions along their edges. The ligule is colourless, and does not become purple. The auricles are colourless in the young stages, and only become purple at flowering. The leaf sheaths are definitely flattened.

This grass grows vigorously in autumn and early winter, and is quickly eaten out under grazing. It appears to thrive especially on the sandy soils of high rainfall districts.

IV.—THE WALLABY GRASSES OR DANTHONIAS.

There is a number of Wallaby grasses, but the common native species of South Australia is mainly *Danthonia semiannularis*.

It grows in the form of perennial tussocks, which will withstand much grazing. Young leaves are soft and narrow, and are covered with numerous short hairs. No auricles are present, but in their place, and extending back to the ligule, are a number of long hairs. (See Fig. 7.) In addition, the leaf blade has two conspicuous parallel lines running down the centre of the upper surface of the leaves.

Fig. 7. Showing the parts important in the identification of Wallaby grass.

These can be conveniently called "train lines," as they appear in the Poa grasses, which are to be mentioned later. The emerging leaf shoot is flattened.

The seed head of the grass is formed from October to December, and is in the form of an open panicle. (See Fig. 8.) Around the seeds there are rings of white glistening hairs, which cause the seeds to cling together when ripe, and which have given the grass the various names Fluffy Top, Silver Top, and White Top. The seed is difficult to harvest and sow because of its fluffy nature.

Wallaby Grass is found on natural unimproved pastures in 8 to 25 inch rainfall country. On the sides of hills, and on hard stony ground it usually dominates. It has a shallow root system, is highly drought resistant, and thrives on very poor soils. With high rainfall or top-dressing with soluble phosphates it is eliminated, because other pasture species respond to a greater extent under these conditions, and thus crowd the Wallaby Grass out.

It produces nutritious fodder through most of the year, and makes its greatest growth in winter. After a summer rain it quickly produces green picking for sheep. In the pastoral areas it is recognised that Wallaby Grass pastures keep the sheep healthy, and produce the highest quality wool. It appears that this grass will always remain the most important species in the large areas of semi-arid pastoral country.

Fig. 8. Wallaby Grass (*Danthonia semiannularis*).
[From Australian Grasses by F. Turner.]

Fig. 9. Spear grass (*Stipa scabra*)

[From the Grasses and Fodder Plants of N.S.W., by E. Breakwell.]

V.—THE SPEAR GRASSES OR STIPAS.

These grasses, like the *Danthonias*, constitute a native group. *Stipa scabra* and *Stipa nitida* are perhaps the commonest spear grasses.

They occur as perennial tussocks which disappear under close grazing. They can be identified by the rolled leaf shoot, prominent hairs near the ligule, and narrow dark-green leaves which are prominently ribbed, and very rough to the touch.

The seed head is in the form of an open panicle. (See Fig. 9.) Each seed is sharply pointed, and supplied with a long bristle or awn. When the bristle becomes moist and then dries, it twists spirally and the seed bores into the soil. In the same way, the skin of animals can be penetrated by the seed.

Spear Grass is often found in association with Wallaby Grass in the semi-arid areas of the State. Spear Grass is also common in saltbush areas. The young growth is palatable to stock, but as the plant matures, the leaves are very coarse and are of low fodder value. The seeds often cause much trouble with sheep, because they penetrate the skin and injure the eyes. Spear grasses are very drought resistant, and will withstand long dry summers.

VI.—KANGAROO GRASS (*Themeda triandra*).

This native grass is worthy of mention. In this species the emerging leaf shoot is flattened, and there are prominent hairs near the ligule. The leaves are broad, and the whole plant is a typical bluish-green colour when young. At maturity Kangaroo Grass assumes a characteristic brown colour.

The seed head is an open panicle, and the spikelets each bear several long, stout, brown and twisted bristles. (See Fig. 10.)

It is an erect perennial, which is drought and fire resistant. However, it is very susceptible to grazing, and thrives only where it is protected from stock. It is frequently seen along railway lines, where it is protected, and in addition receives an occasional scorching.

VII.—THE DACTYLIS GRASSES.

The only one of importance is Cocksfoot (*Dactylis glomerata*). In America it is called Orchard Grass, because it grows in the shade of trees.

It is a tufted perennial with the emerging leaf shoot definitely flattened. Auricles are absent, and a small portion of the leaf blade just behind the ligule is of a cream colour. The rest of the leaf blade is dark bluish-green in colour. The leaf blade is usually broad, with a prominent mid rib. Some varieties are hairless, while others are very hairy. The leaf sheath is strongly flattened in this grass.

The seed head is in the form of an open panicle, and the clusters of spikelets are each supposed to resemble a cock's foot, hence the name. (See Fig. 11.)

Cocksfoot grows mainly in the spring, summer, and autumn, and thus requires a fair summer rainfall, or irrigation during the summer months. It is at its best on heavy, wet soils. In the Gippsland Hills, Victoria, where 40 inches or more of rain is received annually, cocksfoot is highly productive and very resistant to grazing. Where the summer is dry, Cocksfoot is very susceptible to grazing.

It appears that the Murray swamps, portions of the South-East, and probably a few select spots in the Adelaide Hills, are the only parts of South Australia where it will persist.

VIII.—YORKSHIRE FOG (*Holcus lanatus*).

This species can easily be recognised by its very soft and hairy leaves. The emerging leaf shoot is always rolled. Another characteristic feature is the presence of pink veins which run longitudinally on the whitish leaf sheath. When walking over a sward of Fog Grass it feels spongy underfoot.

Fig. 10. Kangaroo Grass (*Themeda triandra*)
[From Australian Grasses by F. Turner

The seed head is in the form of an open panicle, consisting of a large number of small light pink to violet spikelets, which are soft and downy to the feel, due to the numerous small white hairs present.

This grass is also known as "Woolly Holcus" and "Velvet Grass." It is one of the commonest grasses in poor English pastures, and is regarded as a weed there. It is a vigorous perennial which soon forms a mat. Stock have to acquire a liking for it, and it is considered to be of low feeding value. On poor

Fig. 11. Cocksfoot (*Dactylis glomerata*). A. Seed Head. B. Base of leaf blade.
[From Pasture Plants and Pastures of N.Z. by F. W. Hilgendorf.]

wet soils such as are found in the Mount Compass and Meadows districts of South Australia, Yorkshire Fog with Subterranean Clover appears to be promising. Fog Grass produces green summer feed, and thus requires temperate summer conditions.

IX.—THE POA GRASSES.

These are hairless grasses without auricles, and having the emerging leaf shoot flattened. If the leaf blade is examined edge on, the tip will be found to be

Fig. 12. Showing leaf tip of Annual Meadow grass. (1) The tip viewed edge on. (2) The tip looking down on the upper surface.

boat-shaped. (See Fig. 12.) "Train lines" run down the centre of the upper surface of the leaf blade. (See Fig. 12.)

The seed head is in the form of an open panicle consisting of numerous small spikelets.

Fig. 13. Kentucky Blue Grass (*Poa pratensis*).
[From The Grasses and Fodder Plants of N.S.W. by E. Breakwell.]

1. KENTUCKY BLUE GRASS (*Poa pratensis*).—It can be distinguished by its fine leaf, and creeping root stem by which it spreads. (See Fig. 13.) In North America it is one of the most important economic species, being used for both pastures and lawns. It has been described as "the standard pasture grass in the humid portions of the United States, where the soil contains plenty of lime." It requires fertile soils, and temperate conditions, *e.g.*, it grows along the road from Robe to Mount Gambier. It produces a thick sward of feed during autumn, winter, and early spring. It dies down in the summer, and grows again with the first rain. Its exact value as far as South Australia is concerned is not known. It may be of use in providing a continuous turf between such grasses as *Phalaris tuberosa*, especially where the pasture is irrigated.

2. BULBOUS BLUE GRASS (*Poa bulbosa*).—It has the general *Poa* characters, and is a tufted perennial with small dark green leaves, and an underground bulb. It occurs particularly in natural *Danthonia* pastures, and helps to give a small quantity of autumn and winter feed.

3. ANNUAL MEADOW GRASS (*Poa annua*).—It has the general *Poa* characters, and is the earliest winter grass to make its appearance on the Adelaide plains. It is a small annual, with fine light green leaves which are often puckered. It is shallow-rooted, and grows only during the cold wet winter months. It usually forms seed heads very early. (See Fig. 14.)

It is often a nuisance on buffalo and couch grass lawns. Although not of high feeding value, it is welcome in natural pastures because of its vigorous winter growth.

4. NATIVE TUSsock GRASS (*Poa Caespitosa*).—It is a wiry, unpalatable, perennial grass, which occurs on fertile soils, *e.g.*, appears on the heavy black plains of the South-East.

X.—THE BROMES.

These are hairy grasses, with rolled leaf shoots, no auricles, and with no prominent hairs near the ligule. The leaf sheath is entire, that is, the sheath is not split right down one side. This is an important means of distinguishing the Bromes from other hairy grasses, *e.g.*, Wild Oats (see Fig. 15). The seed heads are in the form of an open panicle.

1. PRAIRIE GRASS (*Bromus unioloides*).—Can be distinguished from the other Bromes by its more vigorous growth, large green leaves, and its bulky oval sheath, which is whitish and covered with numerous small white hairs.

It does particularly well on rich loamy soils in a good rainfall. It produces a large bulk of succulent, highly nutritive fodder in the winter. It is an annual, but may be a biennial under favorable conditions. It is adapted to cutting, and not grazing. If sown with lucerne it will provide feed when the lucerne is dormant. Unless handled very carefully, it is quickly eaten out by stock.

2. SOFT BROME (*Bromus hordeaceus*) and MADRID BROME (*Bromus madritensis*).—These Bromes have narrow round sheaths. Soft Brome is uniformly hairy on the sheath and leaf blade, while Madrid Brome is more hairy on the leaf blade than on the sheath. In addition, Soft Brome can usually be distinguished by its bitter taste. The spikelets of Madrid Brome bear numerous long bristles, while those of Soft Brome are almost awnless. (See Fig. 16.) These grasses are common on top-dressed natural pastures, where they gradually replace *Danthonia*. Where a perennial grass has not been sown with Subterranean Clover, these grasses soon make their appearance, and indicate increased fertility of the soil.

They are annuals, and have a low feeding value at maturity because of the bulk of inedible seed produced.

Fig. 14. Annual Meadow Grass (*Poa annua*)
 [From *The Grasses and Fodder Plants of N.S.W.* by E. Breakwell.]

XI.—WILD OATS (*Avena fatua* AND *Avena barbata*), BARLEY GRASS (*Hordeum murinum*), AND CAT'S TAIL GRASS (*Koeleria phleoides*).

Although not in the same botanical group, these three annual hairy grasses with rolled leaf shoots can be classed together for the sake of convenience. Like the Bromes, they have no prominent hairs near the ligule, and unlike the Bromes, they have a split leaf sheath. (See Fig. 15.)

Fig. 15. Showing (1) Entire leaf sheath of the Bromes. (2) Split leaf sheath of Wild Oat.

Fig. 16. Showing the spikelets (natural size) of the three most common Bromes. (1) Prairie grass. (2) Soft Brome. (3) Madrid Brome.

1. WILD OAT.—Is not always hairy, hairless forms often being found. It always has a characteristic dark-bluish green colour. It is a common weed in cereal crops, and occurs particularly in the better cereal country. In the pasture year of a rotation, Wild Oats is very useful, because it is leafy, palatable, and a strong winter grower.

Fig. 17. Red Fescue, Chewing's Fescue (*Festuca rubra*).
 [From The Grasses and Fodder Plants of N.S.W. by E. Breakwell.]

2. **BARLEY GRASS** is always hairy, and can be distinguished by its pair of auricles or claspers. Like Wild Oats, it is associated with cereal cultivation. It has a high fodder value in the early stages, but once it flowers it is of no use because of the sharp inedible seed formed, and the low palatability of the stems and leaves.

3. **CAT'S TAIL GRASS.**—The leaf sheaths are covered with long silky hairs. It forms a green compact seed head, which resembles a cat's tail in miniature. The grass is widely spread, and is of little value.

XII.—THE SHIVERY GRASSES, OR BRIZAS.

Large Shivery Grass (*Briza maxima*) and Lesser Shivery Grass (*Briza minor*) are small annuals which occur on cultivated land in winter. They are hairless, with rolled leaf shoots, and are light-bluish green in colour. Young Shivery Grass plants can easily be confused with those of *Phalaris tuberosa*. However, when the young stems are cut near the base the sap of the shivery grasses is colourless, while that of *Phalaris* is always reddish or purplish. *Brizas* are of little grazing value.

XIII.—THE FESCUES OR FESTUCAS.

1. **CHEWING'S FESCUE** (*Festuca rubra* var. *Chewings*), (see Fig. 17), **Hard Fescue** (*Festuca duriuscula*), **Red Fescue** (*Festuca rubra*), and **Sheep's Fescue** (*Festuca ovina*) all possess very fine hairless leaves, and have the emerging leaf shoot flattened. Because of their thin leaves they are well adapted to lawns, golf

Fig. 18. Showing characteristically-shaped leaf, and creeping stem of Creeping Bent.

links, tennis, bowling and croquet greens. They are valuable perennial pasture grasses on poor soils in New Zealand and Great Britain. In South Australia the fine leaved Fescues do not appear to have any value as pasture grasses.

2. **TALL FESCUE** (*Festuca elatior*) and **Meadow Fescue** (*Festuca pratensis*) are broad-leaved perennials which have done well in damp and marshy situations in Queensland and New South Wales. They are pastured or cut for hay. Like the fine leaved Fescues, they do not appear to be of use in South Australia.

3. **SILVER GRASS** (*Festuca Myuros*).—This is a very common annual grass in natural pastures, particularly those which are top-dressed. It has thin needle-like leaves, thin stem, purple sheath base, no auricles, and characteristic silvery green colour. It has a very low feeding value after flowering.

XIV.—THE BENTS, OR AGROSTIS GRASSES.

In general they are hairless perennial grasses with rolled leaf shoots and characteristically shaped leaves, which are broad at the base and rapidly come to a point at the tip. (See Fig. 18.) The best known Bents are:—

Red top (*Agrostis palustris*), **Creeping bent** (*Agrostis stolonifera*), and **Waipu Brown top** (*Agrostis tenuis*). Waipu Brown Top is often used in lawns, and is promising on the light soils of the "Ninety-mile desert." This group is of no use for South Australian pastures. In the cold wet regions of the world the Bents thrive on poor sour soils.

XV.—A MISCELLANEOUS GROUP OF GRASSES WHICH ARE NOT RELATED BOTANICALLY.

1. WEEPING LOVE GRASS (*Eragrostis curvula*).—It has a rolled leaf shoot, no auricles, and prominent hairs near the ligule. In addition it has fairly coarse leaves, and the seed head is typically an open panicle with small dark-coloured spikelets (see Fig. 3.)

This perennial appears at its best on light sandy soils in good rainfall districts, where it spreads easily from seed. In addition, it possesses undoubted drought resistance. This grass may be of use in semi-arid areas of the State.

2. MANY-FLOWERED MILLET GRASS (*Oryzopsis miliacea*).—It is a hairless perennial, with a rolled leaf shoot, no auricles, and often has hairs near the ligule. It can be recognised by its broad, dark-green leaves and coarse stems. The seed head is in the form of an attractive, open, spreading panicle, with small light-brown spikelets. (See Fig. 19.)

Fig. 19. Many-flowered Millet Grass (*Oryzopsis miliacea*).
[From The Grasses and Fodder Plants of N.S.W. by E. Breakwell.]

This grass has sometimes been called "veldt grass." It is very drought-resistant, and produces green picking for stock during the summer months. The leaves are palatable even when mature. It appears that this grass could be of use in the semi-arid areas of the State. Mr. D. A. Brooks, of Booleroo Centre, has great faith in this grass for his district. It is hard to establish, and would require careful handling to prevent eating out by stock.

3. GOLDEN CROWN GRASS (*Paspalum dilatatum*).—It is a perennial grass with a rolled leaf shoot, no auricles, hairs near the ligule, and strongly flattened leaf sheath. The leaves often show a purplish colouration. It has a characteristic seed head, which consists of three or four spikes arranged along the stem. (See Fig. 20.)

This grass has wide succulent leaves, and requires plenty of moisture and heat for rapid development. It is summer growing, and is dormant in the winter. It has played a very important part in the development of dairying in the coastal areas of New South Wales.

In South Australia *Paspalum* is common as a weed along channels and in Lucerne stands of the Murray Irrigation areas. There seems to be no point in developing it in these areas because better pasture species are available.

4. COUCH GRASS (*Cynodon dactylon*) and KIKUYU GRASS (*Pennisetum clandestinum*) are two perennial grasses with creeping stems. They both have hairs near the ligule, and have flattened emerging leaf shoots. Couch grass has small dark-green leaves, while Kikuyu grass has large light-green leaves.

Fig. 20. Showing seed head of Golden Crown Grass.

- (1) Couch grass is valuable as a pasture grass on light soils and river flats under sub-tropical conditions. In South Australia it has been used as a sand-binder, at the same time providing useful feed in summer and early autumn, especially when good summer rains obtained.
- (2) Kikuyu grass is also highly productive under sub-tropical conditions. It is a summer grower, and is dormant during the winter. It shows drought resistance, and may be of use for sandy soils of our higher rainfall districts. It does not form seed here, but readily strikes from rooted cuttings. In New South Wales bracken fern has been controlled by using Kikuyu grass in conjunction with stock. It is being used successfully for lawns in South Australia.

5. WEEPING GRASS OR MEADOW RICE GRASS (*Microlaena stipoides*).—This is a perennial native grass with a rolled leaf shoot, pair of auricles, and hairs near the ligule. It can be recognised by its characteristic dark-bluish coloured leaves, which appear to come from below the soil, because of its underground creeping stems. It is very common in the Adelaide Hills and South-East, and forms a turf. It is persistent under grazing, and provides a small amount of soft succulent feed during the year.

(To be continued.)

REVIEW OF THE 1934 FRUIT DRYING SEASON.

[By F. R. ARNDT, Horticultural Instructor for the River Murray Irrigation Areas of South Australia.]

A Paper read at the Conference of River Murray Branches of the Agricultural Bureau held at Barmera on June 22nd, 1934.

The 1934 fruit drying season, so far as applied to the South Australian Irrigation Areas, has in many respects been a rather unusual one. Climatic conditions during January were hot and dry, but in February were somewhat more temperate in character. March will long be remembered for its record heat wave, but when this had run its course, a month of remarkably cool and dull weather followed, which in its turn was succeeded by a warm and rainless May.

Spreading Sultana Grapes on to Drying Racks.

QUALITY OF FRUIT.

These fluctuations of temperature had a considerable influence upon the quality of fruit and upon drying operations. The warm weather during January had the effect of ripening the fruit somewhat earlier than usual, as sugar tests showed that Currant and Sultana grapes had developed a higher sugar content than was the case for the corresponding period of the previous year. The fruit was also of good colour early in the season, but darkened considerably on the vines as the season advanced, chiefly on account of the hot climatic conditions then prevailing. An additional irrigation during the hottest period—if this could have been worked in—would, no doubt, have enabled the vines to maintain the quality of their fruit for a longer time. Some damage to the fruit from rain, caused by scattered showers, occurred in places, but on the whole little rain fell during the drying period, although in April light showers occurred, and the weather remained cool and dull for the greater part of the month, necessitating the dehydration of much of the fruit.

DIPPING METHODS.

The Cold Potash Dip.—Little fruit that had been processed by the cold potash dip came under the writer's notice during the past season. This dip has never been very popular with South Australian sultana growers, and does not appear to be gaining in favour. This is no doubt greatly due to the fact that to obtain satisfactory results from this process it is necessary to have both first class fruit and good drying weather. Good weather conditions are an essential factor in the successful drying of potash-dipped fruit, as on account of the heavy concentration of potash used in this dip (25lbs. to 50galls. of water), the fruit naturally has a large amount of chemical adhering to it while it is drying on the racks, which during damp weather absorbs a considerable quantity of atmospheric moisture, whereby the drying rate of the fruit is retarded and the colour darkened.

Again, fruit that has been partly damaged on the vines, either by heat or rain, does not produce a satisfactory sample when processed with this dip, for although the unspoilt berries dry out a bright golden colour, those adversely affected by the weather turn a much darker shade when dried, thus giving the finished product a mottled appearance.

Probably the greatest drawback, however, found by growers in the use of this dip is the time taken in the drying of the fruit, which under favourable conditions is usually from two to four days more—and during bad weather often much longer—than is the case with fruit processed by the Standard Mixed Dip. Another factor that does not add to the popularity of this dip is the washing of the fruit when dried, and to save time and expense some growers omit this altogether. This, however, is a mistake, for not only does washing remove much of the surplus chemical from the fruit, but it also has the effect of brightening the colour of the fruit considerably.

Briefly summed up, then, the reason why the Cold Potash Dip has not become more popular with South Australian sultana growers is due to the fact that compared with other dips the fruit takes longer to dry, darkens more on the racks during damp weather conditions, and tends to produce a more mottled sample with fruit that is not of quite first class quality. The general opinion of growers—that to obtain satisfactory results with the Cold Potash Dip it is necessary to have both first class fruit and good drying weather—is in the main a correct one.

THE STANDARD MIXED DIP.

The great bulk of the fruit during the past season was processed by means of the Standard Mixed Dip. This method consists of immersing the fruit at temperatures ranging between 177° and 183° Fahr., in a solution made at the rate of 2½lbs. Carbonate of Potash, 1½pts. of Olive Oil, and sufficient Caustic Soda to slightly crack the fruit.

Where the fruit was of good average quality and processing operations were carried out correctly, this dip generally gave good results, but as was the case with the other dips, the fruit also darkened when weather conditions were unfavorable, but usually not to the same extent as that treated by the Cold Potash Dip.

Towards the end of the season when the weather had become cool and the fruit was no more of first class quality, a number of growers raised the temperature of this dip to 190° Fahr. This temperature produced a somewhat darker but more even coloured sample of dried fruit, than when a lower degree of heat was used in the dip, and generally gave satisfactory results under the conditions then existing.

THE MODIFIED HOT CAUSTIC SODA DIP.

In order to dry the fruit more quickly and to obtain a more even—although darker—colour with partly damaged fruit, some growers reverted to the hot Caustic Soda Dip in the processing of their fruit. Fruit so treated generally

dried to a slightly darker shade under the same conditions than where carbonate of potash was an ingredient of the dip, but the colour obtained was usually of a fairly even nature.

THE BOILING CAUSTIC SODA DIP.

In some instances where weather conditions were unfavourable, the old boiling Caustic Soda Dip was used again. The Gordo was usually the variety of fruit so treated, but small quantities of Sultanas were also processed by this dip. The main object aimed at by the use of this dip—that of quick drying—was often not attained, as the high temperature usually cracked the fruit so severely that a considerable amount of sugar escaped on to the outside of the berries and covered them with a sticky film which retarded drying, and such fruit had often first to be washed before it could be satisfactorily dried.

The Caustic Soda Dip at a temperature of about 200° Fahr. generally gave satisfactory results in the processing of Gordos, and did not render the fruit nearly as sticky as when the boiling dip was used.

REMOVING THE GREEN TINGE FROM THE FRUIT.

Overseas buyers having shown their preference for golden coloured fruit as against that with a greenish tinge, the various packing companies along the River have urged their growers to make every effort to eliminate this later class of fruit.

Double Dip Tank and Draining Boards used in the processing of Sultana Grapes.

To do this successfully, it is first of all necessary that the fruit should not be picked before it is fully ripe. In the series of Sultana Drying Experiments conducted by the writer with officers of the C.S. and I.R. several years ago, it was shown that to obtain a good golden coloured sample of dried fruit, it was necessary that the fresh fruit should not be under 11° to 12° Beaume when picked. Fresh fruit having a sugar content lower than this dries out with a greenish tinge, which, however, may to some extent be removed by bleaching the dried product in the sun.

SUN DRYING ON HESSIANS.

The fruit after its removal from the drying racks is, of course, spread on to hessians placed in the sun to complete the drying process.

With fresh fruit of good colour and sugar content—provided that drying operations have been correctly carried out, but little trouble is experienced, as such fruit will naturally dry to a good golden colour. But with fruit that has the green tinge on it after its removal from the racks, it is often necessary to resort to various expedients to remove this. This may often be done by rolling the fruit in heaps while on the hessians, covering it with the hessian, allowing it to sweat for a couple of hours during the heat of the day, and then spreading it out again.

Should this operation fail to remove the green tinge, the fruit may be sprayed either with clean water or a Light Potash Solution, rolled up in heaps on the hessians and allowed to sweat for several hours, after which it is again spread out. This method will generally help to remove the green tinge from the fruit, but on fruit that was not sufficiently ripe when picked the resulting colour will often be a light brown rather than a golden shade.

One thing, however, that under no circumstances should be omitted is the perfect drying of the fruit before it is boxed, as fruit insufficiently dried and containing a considerable amount of moisture deteriorates in colour and quality after being packed much more quickly than that which has been well dried.

TREATMENT OF FRUIT ATTACKED BY MOULD.

During periods of damp weather, as experienced during the past season, the fruit is at times attacked by mould while it is on the racks, which in the first instance may have developed on rain damaged berries while still on the vines, or have begun its ravages after the fruit had been placed on the racks.

The spread of mould on the racks is often aided by undue shading of the fruit during dull weather, and the first thing to do as soon as it has been discovered is to remove the side curtains (provided that no driving rain is occurring at the time to wet the fruit) and let in as much light and air as possible to check the fungus from doing further damage. Sultanas and Gordos attacked by mould are generally benefited by being sprayed with the Standard Cold Dipping Solution, made up at the rate of 1lb. of Carbonate of Potash to 2galls. of water to which has been added about 1oz. of Olive Oil. To prevent undue concentration of moisture on the fruit, the best time to spray is in the morning after the night dews have departed, which will also give time for the moisture applied by the spray to evaporate before the evening, and so not remain on the fruit during the night.

CONDITIONS NECESSARY FOR SUCCESSFUL DRYING OPERATIONS.

In the writer's opinion the chief factors that govern the successful drying of Sultana grapes in a season like the past one are briefly as follows:—

1. *Sufficient Rack Room.*—Before the drying season commences the grower should see that he has sufficient rack room so that he will not need to fill his racks more than twice, even with a good crop, and with a moderate one only require to use some of them a second time. Of course, sufficient rack room to hold the whole of the crop with one filling would be the ideal condition to attain, but with the present low prices of dried fruit few growers can afford to do this.

2. *Picking of Fruit.*—The fruit should be quite ripe when picked and should register not less than 11° Beaume for an early picking, but 12° Beaume will give a plumper sample of dried fruit.

3. *Separate Pickings.*—Different classes of fruit, such as sun scorched or rain damaged fruit, should either be picked at different times or placed into separate

buckets to that of fruit that is of first class quality, and should be dried partly on the racks.

4. *The Standard Mixed Dip.*—For all general purposes with fruit of average good quality, the Standard Mixed Dip should be used for dipping Sultana grapes at a temperature as nearly as possible to 180° Fahr.; but during cold or moist weather the temperature of the dip may often with advantage be raised up to 190° Fahr.

5. *The Dipping Solution should be Kept Clean.*—Where 500 to 1,000 tins are immersed in a dipping solution of 60galls. to 80galls. per day, the dip should be cleaned daily. A larger dip need not, of course, be cleaned so often for the same quantity of fruit treated as a smaller one. A dirty dip does much to deaden the colour of the fruit.

6. The fruit should be spread thinly on the racks, as the drying process is thereby facilitated. Heavy loading often leads to the development of mould on the fruit, if weather conditions are damp and cloudy.

7. *Shading of Fruit on Racks.*—To prevent the fruit from being darkened by the sun, the sunny sides of the racks should be shaded on hot days when the temperature reaches above 90° Fahr. in the shade. During moderately warm or cool weather—provided that there is no rain—the side curtains of the rack should not be used; this unduly prolongs the drying period, and may even lead to the development of mould with fruit that has been damaged by rain while on the vines.

Finishing off on Hessians.—The fruit should be left on the racks until cured—that is, sufficiently dry to be taken off without being damaged—after which it should be spread thinly on hessians placed in the sun and left there until perfectly dry. It is essential for fruit to be perfectly dry if it is to keep its colour and quality for any length of time, and as it is often many months in store before being sold, it is to the grower's interest to see that his fruit is in that condition before it is delivered to the packing shed.

Roseworthy Agricultural College.

Annual Winter School for Farmers, 1934.

The Annual Winter School for Farmers will be held at Roseworthy Agricultural College from the morning of the 8th August to the morning of the 17th August.

A comprehensive course of lectures and demonstrations is being arranged. The Minister will open the School on the 8th August, and Mr. McCann, the S.A. Trade Commissioner in London, who is at present visiting South Australia will lecture the School. Others lecturing the School include the Director and members of the Walte Institute Staff, Officers of the Department of Agriculture and the Principal and Staff of the College.

Arrangements with outside lecturers are not yet complete.

Conditions for enrolment have been circularised to all branches of the Agricultural Bureau; non-members of the Bureau will be supplied with these on application.

ALLAN R. CALLAGHAN, Principal.

SOME NOTES IN GENERAL ON THE CONSTRUCTION OF BUILDINGS.

[By T. A. MACADAM, Dip. Arch. (Glas.), A.R.A.I.A., Lecturer in Architecture and Building, School of Mines, Adelaide.]

(Continued from June issue, page 1387.)

CEILINGS.

The first portion of these "notes" finished with the ventilation under the floor. Ceilings are considered next, and here we find modern materials have simplified the construction of ceilings. The old lath and plaster ceiling is rarely used now, and fibrous plaster, asbestos, or any of the insulating materials takes its place. All of these materials are made in sheets 3ft. and 4ft. wide, and from 5ft. to 10ft. in length. Each sheet should have centre fixing as well as at the ends and sides. The joints between the sheets are covered by strips of wood, say, 2in. x 1in., which give a panelled effect to the ceiling. These ceiling materials may be coloured or left in their natural state. Small fluted galvanized iron is also used for ceilings, and when coloured gives quite a good appearance.

PLASTERING.

To put plaster on walls and get a smooth and even surface is a plasterer's job, but there may be cases where a fair surface will serve the purpose, and this could be done as follows:—Slake the lime carefully, and then pass it through a fine sieve to keep back any unslaked particles. Form a round basin with sharp sand which has been passed through a fine sieve, and into the basin of sand pour the slaked lime, taking care that no lumps are put into the mix. Next add 1lb. of hair to every 3 cub. ft. of the mixture or in the proportion of 1 bag of hair to every bag of lime. Cow hair may be used, and should be long. Mix the sand, lime, and hair together thoroughly, then rake and leave for 14 days before using. When ready for use, damp the walls which are to be plastered and apply the plaster, $\frac{3}{4}$ in. in thickness, on the walls and bring it to an even surface. This first coat serves as a key to the second coat, which is composed of two parts of sand to one of slaked lime. Before this is applied the first coat should be well wetted and cleaned. The first coat should be firm but not set before the second coat is put on, and should be scratched to form a key for the second coat. Trowel the second coat to as even a surface as is desired.

Where walls have to stand knocks the surface should be cemented and not plastered. Any walls which are likely to get wet should be cemented.

PLUMBING.

Plumbing is a trade which should be done by an experienced man, but there are a few points which the property owner can look after if there are any drains or plumbing fittings.

Drains should be kept clear, and to do so it is advisable to keep as much grease as possible from entering them. Grease should be collected separately and buried. Where there are any fittings such as sinks, &c., the connections below them should be examined and cleaned occasionally. Fittings usually have a screw eye for cleaning purposes. On the drain pipes will be found inspection eyes where the drain can be examined. If new drains are being laid keep them away from tree roots, heavy traffic, and the foundations of any building. A plan of the drainage system should be kept on the property, so that when a choke occurs there will be no delay in finding it.

SEPTIC TANKS.

In some farms septic tanks are installed, and there may be others where the septic tank system of drainage may be installed later. The position of the tank on the site is important, as it must be placed in such a position that the drains leading to it will have a fall of 1ft. in 40ft. Another factor in the placing of the septic tank is the relation it will have to any well or underground tank. Care should be taken to avoid any outlet from the septic tank soaking through the soil towards any underground water supply. A well should be placed, if possible, three times its depth from the outlet of the septic tank.

PAINTING.

This is a job that the farmer can do if he has the tools and materials. He will find it will pay to keep his woodwork and ironwork (not including galvanized iron) well painted, as it lengthens the life of both considerably, in addition to improving the appearance.

Before commencing painting see that the surface to be painted is clean. Mixed paints can be purchased in all tints, and where a small quantity is required it is cheaper to purchase it.

In painting new woodwork begin with a coat of priming, which is a mixture of white lead, red lead, and oil. If the woodwork is inside then the following proportions may be used:—4lbs. of white lead, 2ozs. of red lead, and 2 pints of raw linseed oil. For outside woodwork the proportions are 4lbs. of white lead, 2lbs. of red lead, and 1 pint of boiled oil. The quantities stated will cover about 30 sup. yds. Note that boiled oil is used for outside and raw for inside. This priming coat should be applied to the woodwork as soon as it is exposed to atmospheric conditions. It is only applied to dressed timber, that is, timber with a smooth or "dressed" surface. Flooring boards are an exception.

After the priming coat the next coat of paint consists of the following:—5lbs. white lead, 1 pint of boiled linseed oil (for outside), $\frac{1}{2}$ oz. of driers, and $\frac{1}{2}$ pint of turps. One ounce to 2ozs. of colouring matter such as ochre, umber, etc., should be added for every 10yds. to be painted, depending on the tint required.

For inside woodwork raw oil would take the place of the boiled oil, and the driers would be increased to 1oz.

Each succeeding coat would be similar except that the colouring matter may be varied.

Where woodwork is very exposed, such as on the top of roofs or on top of gables four coats should be given, and every third year it should be repainted. The more frequently paint is applied the easier it is done, and less paint is required.

When painting galvanized iron one coat will be found to be sufficient, but galvanized iron should not be painted unless there is a special reason for doing so. Iron roofs are sometimes painted for appearance, and when painted white the temperature inside the roof is lowered. Special white paints are obtainable for roofs.

LIMEWASHING.

As lime washing or whitewash is used by farmers, a method of preparing it is given. Take a clean, watertight barrel and put $\frac{1}{2}$ bush. of fresh lime into it. Slake it by pouring water over it hot and in sufficient quantity to cover it 5in. deep. Stir it briskly until thoroughly slaked. When slaking has been effected, dissolve it in water, add 2lbs. sulphate of zinc and 1lb. of common salt. These will cause the wash to harden and prevent it from cracking.

If cream colour is desired add 4lbs. to 6lbs. of ochre for every bushel of lime. If stone colour is wanted then add 6lbs. to 8lbs. of raw umber and 3lbs. to 4lbs. of lamp black.

SKETCH - H.

Whitewash is improved by adding 1lb. of pure tallow (free from salt) to every bushel of lime.

WOOD AND IRON BUILDINGS.

Few farms are without some buildings which are constructed of wood and iron, and as the construction varies considerably from that of the brick or concrete type a few notes may be helpful.

Foundation.

Beginning with what is called the stump type of foundation we have a series of wooden stumps, say, 4in. x 4in. or 6in. x 6in., placed at intervals in the ground to a depth of 18in. to 24in. and projecting above the ground about 12in. to 15in. (see Sketch H). A soleplate about 6in. x 2in. is sometimes fixed to the bottom of the stump, and angle struts put in position as shown in Sketch F.

After digging the hole for the stump wet it before placing a 4in. bed of concrete at the bottom of it. On the concrete set the stumps in position, and surround with 6in. of concrete to above ground level. The concrete protects the timber from damp and white ants in addition to strengthening the stump as a foundation. Stumps are placed at 4ft. or 5ft. centres, and on the top of each stump is

· SKETCH · F ·

· SKETCH · G ·

placed (not fixed) an ant cap, which is a piece of flat galvanised iron turned down at an angle on all sides and projecting beyond the face of the stump about 2in. This is to prevent the white ants from reaching the woodwork above the stumps. Jarrah or any other hardwood should be used for the stumps and all woodwork near the ground. An additional precaution against white ants is to treat the stumps, &c., with a white ant solution.

When setting stumps in position see that they are true vertically and horizontally. If cement concrete is used protect it from drying too rapidly.

On top of the ant caps are laid the bearers (see Sketch H). Note that neither the ant caps nor the bearers on top of them are fixed to the stumps as any nail holes would give the ants access to the timber.

Wall Construction.

The corner studs or posts are next placed in position and bolted at the foot to the bearers, and temporarily stayed. Where thick or heavy timbers are joined together they should be bolted, not nailed. The cross bearers at the ends can be set in position, and then the floor joists. It frequently happens that joists have a curve in their length which makes them unsuitable for a floor. To get rid of the curve lay the joist in the position it is going to be fixed, and turn it with its back uppermost. Mark the joist where it bears on the bearer or plate, turn it over,

and put a saw cut diagonally to within $\frac{1}{2}$ in. of the top face. See that the saw cut will be over the bearer when fixed, as shown in Sketch J. This method will remove any spring in the joist, and make it more level when fixed. Space the joists at 18 in. centres, and fix them to the bearers with 3 in. rose-headed nails. In Sketch H will be seen the relation of the various timbers. On top of the joists (at the ends) the bottom plate is laid and fixed to the floor joists. This plate extends the full length on the one side and on the other as far as the doorway. At door openings it is omitted to allow the door sill (which is thicker than the plate) being placed level with the floor. The wood sill should be 3 in. jarrah and rounded on the outer edge. On the bottom plate is fixed the wall studs, which

may be 3 in. x 2 in. or 4 in. x 2 in. at 18 in. to 24 in. centres, depending on the material used for covering them. If material is in sheets 3 ft. wide the studs would be at 18 in. centres, and if 4 ft. sheets then 24 in. centres.

At the two ends of the building (see Sketch H) a bearer takes the place of the floor plate, and the studs are cut over it and securely nailed to it. The studs should be continuous from bottom plate to top plate if possible, and should be braced as shown with 3 in. x 1 in. wood braces let flush into wall studs and nailed to same. Where practicable the braces should be fixed at a steep slope. Braces at the corners should continue to top of corner posts.

Where window or door openings occur they should be placed, if possible, so that the minimum number of studs will be cut to make room for them. At the top and bottom of window openings put a cross rail to trim the intermediate studs, and frame the opening.

SKETCH K.

SKETCH L.

In Sketch H portion of the top plate is shown in relation to the corner posts. Where the plates meet on the corner post they should be half checked together and strapped to corner post as shown on Sketch K. The top plate should be continued around the building on all sides and at the same level, as this assists

greatly in tying the walls together at the top (see Sketch L). Where a gable is introduced the woodwork of the gable should not be formed by continuing the wall studs to under side of roof. Stop the wall studs under the top plate, and put fresh studs on top of the plate to form the walling of the gable.

Wall Covering.

In Sketch H portion of the wall studding is shown covered with weatherboards. These should be fixed to the studs with one nail at each stud. Galvanized weather-board iron is also used as an outside wall covering. This has the appearance of

weatherboards when painted. It makes a building warmer in summer, but has the advantage of requiring much less painting than wood. Corrugated galvanized iron is used in a similar manner with the flutes running horizontally or vertically.

TOP SPECIAL SUPER

"GIVE IT A SPIN."

The Adelaide Chemical & Fertilizer Co., Ltd.

When flutes are vertical as shown in Sketch H 3in. x 2in. rails are introduced about every 3ft. in height, depending on the size of the sheets of iron used, and it will be seen in the sketch that every alternate stud may be omitted. Should the inside of the walls be lined then the intermediate studs would have to be retained.

Asbestos sheets are also used for lining the walls outside and inside. When used externally place the sheets vertically. When the sheet is continuous from the bottom of the wall to the top, the sheets have to be joined in the height and a horizontal joint is made, then a strip of galvanised iron should be placed at the joint to prevent the rain which falls on the face of the upper sheet getting inside the sheet below (see Sketch M). A wood cover mould which covers the joint will cover the iron also. Fix the sheets with galvanised clouts. Care has to be exercised when nailing asbestos sheets as the

· SKETCH · P ·

· SKETCH · N ·

material is brittle. A good plan is to drill the holes for the nails. The joints between the sheets should be at the studs or rails so that proper fixing is obtained for the sides and ends of the sheets and for the wood batten which covers the joints. Over all joints is placed a wood batten about 2in. x 1in. and, in addition to covering the joints between the sheets, it gives a panelled effect on the walls.

Flooring.

Laying the flooring boards is a simple operation, and needs little comment. Lay the first flooring board at door opening with the groove facing the room. Trim this board to the line of wall if room is not square. Nail to the joists with 1½in. oval steel brads 1½in. long or rose-headed nails. Nail on the angle as shown on Sketch P and about 1in. from the edge. Lay the next three boards and cramp them into position. A crowbar will be found useful for cramping. When cramped up tight nail the boards and proceed with the next three boards. Where boards have to be joined in their length the joining should take place over a joist as shown in Sketch N. Jarrah flooring boards are from 3½in. to 4in. wide and ¾in. in thickness.

(To be continued.)

DEPARTMENT OF AGRICULTURE.

Bulls that are purchased under regulations of the Dairy Cattle Improvement Act, and upon which Government pays a subsidy, are available, for two years after purchase, to serve a certain number of outside cows.

The following list, compiled by the Department of Agriculture, shows the names of such bulls and of the people who own them, and indicates also the months until which the respective owners will be prepared to make the services available.

As will be noticed, the distribution of subsidised bulls is now fairly general throughout the State; hence, many of those persons, who in the past have found it difficult to get the use of a good bull, should not have much similar trouble in the future. And here let it be stated that everyone of these subsidised animals is a registered pure-bred and from a dam of proved productivity under Government official test.

The maximum service fee is 10s. per cow.

For the information of cowkeepers, it is pointed out that, although the addresses as given in the following list are those to which application should be made for the services of the bulls, the bulls themselves may, in a few instances, be located elsewhere.

EXPERIMENTAL FEEDING TESTS CONDUCTED AT PARAFIELD POULTRY STATION.

[By C. F. ANDERSON, Poultry Expert.]

A series of feeding tests are being conducted at Parafield Poultry Station with a view to ascertaining if suitable foods which are obtainable on the majority of our farms can be satisfactorily fed to poultry. The tests are each of 50 White Leghorn pullets, and commenced on April 1st, 1933.

The feeding is as follows:—

No. 1 Test.—Morning—Wet mash composed of 1 part crushed barley, 2 parts wholemeal (by weight), $\frac{1}{2}$ lb. meat meal, 50 per cent. chaffed greenfeed.

Midday—1oz. wheat per bird.

Night—1oz. wheat per bird.

No. 2 Test.—Dry mash composed of same proportions as No. 1 Test.

Midday—Greenfeed.

Evening—Wheat.

No. 3 Test.—Morning—Wet mash composed of 1 part bran, 2 parts pollard (by weight), $\frac{1}{2}$ lb. meat meal, 50 per cent. chaffed greenfeed.

Midday—1oz. wheat per bird.

Night—1oz. wheat per bird.

No. 4 Test.—Morning—Wet mash composed of 1 part bran, 2 parts wholemeal (by weight), $\frac{1}{2}$ lb. meat meal, 50 per cent. chaffed greenfeed.

Midday—1oz. wheat per bird.

Night—1oz. wheat per bird.

No. 5 Test.—Morning—1 $\frac{1}{2}$ ozs. wheat per bird.

Evening—1 $\frac{1}{2}$ ozs. wheat per bird.

Greenfeed in season.

The following are the numbers of eggs laid by each pen from April 1st, 1933, to May 31st, 1934.

Definite conclusions, however, cannot be given at this juncture with regard to the various methods of feeding. It is necessary for the tests to complete the 24 months before any satisfactory opinions can be formed.

	No. Eggs Laid April 1st, 1933, to May 31st, 1934.	No. Eggs Laid Month of June, 1934.	Total Eggs Laid April 1st, 1933, to June 30th, 1934.
No. 1 test	7,963	366	8,329
No. 2 test	7,437	344	7,781
No. 3 test	6,971	407	7,378
No. 4 test	8,405	344	8,749
No. 5 test	3,552	203	3,752

OFFICIAL POULTRY TEST EGG-LAYING COMPETITION, 1934-35.

CONDUCTED AT PARAFIELD POULTRY STATION.

ONLY FIRST GRADE EGGS RECORDED.

SECTION 1.—WET MASH.

Class No. 1.—White Leghorns.

PAPERS READ AT CONFERENCES.

POULTRY KEEPING IN CONJUNCTION WITH A FRUIT BLOCK.

[W. MACGILLIVRAY, Barmera.]

River Murray Conference, Barmera, June 22nd, 1934.

It is with some trepidation that one advocates any form of industry in these years of depression, quotas, and restrictions, but as the depression seems to be equal in all primary as well as secondary industries we at least have a level to work on. Possibly the most prosperous of all primary industries in Australia to-day is the production of dried fruit, and this has been made possible by the organisation within the industry itself. The egg industry has also a certain amount of organisation, but unfortunately not so complete as that of the dried fruits. New South Wales had until recently a compulsory pool covering the areas which were the chief egg producers in that State, and they are now running a voluntary pool with a considerable amount of success. Their organisation means that the New South Wales poultryman obtains between 5d. and 6d. a dozen more for his eggs than does the poultryman in South Australia.

At the present time most of the commercial eggs in this State are produced in suburban areas round Adelaide, on highly priced building allotments, with their attendant high rates and taxes, &c. At different times I have made tours of these poultry yards and could not help but admire the skill and attention given by the owners to keep their flocks in good condition in such restricted spaces where neither air or sunlight could have free access.

Recently I had the pleasure of showing one of Adelaide's leading poultrymen round the Berri and Barmera districts, and he was so impressed with the ideal conditions for poultry keeping around here that he said if we took up the industry seriously the poultrymen in Adelaide could not compete with us. I mention this because a number of people seem to think that in order to make poultry keeping a success it is necessary to be in or near Adelaide.

As this paper is intended to take poultry keeping in conjunction with fruit growing, the first heavy overhead expenses of the commercial poultry-keeper would not have to be met, namely, several hundred pounds for land, with its attendant high taxation charges; this would be borne by the fruit block in any case. An ample supply of greenfeed is essential to keep the flock in health and well up in egg production, and this every blocker can get in its very best form, in the shape of lucerne, in practically unlimited quantities, incidentally greatly reducing the cost of feeding, and should a cow be kept, the skim milk fed in the wet mash will further reduce feeding costs, and greatly aid egg production. When carting lucerne, leaf accumulates on the bottom of the trolley and also around the haystack. This should all be carefully bagged as the most valuable part of the hay, and can be fed to the birds in their mash should greenfeed be scarce at any time.

The foregoing are some of the obvious advantages a fruitgrower would have on taking up poultry keeping, but the most important of all is apt to be overlooked, and that is the wonderful winter climate with its attendant sunshine. There is nothing like sunshine for keeping flocks in healthy, vigorous condition, and conversely there is nothing like dull wet weather for spreading disease and reducing egg production. You, who know the Adelaide winter climate, as well as our local one, can readily see what this means to the poultry keeper, for it is in winter his eggs command the top price of the year.

CHOICE OF BREEDS.

Should a fruit grower decide to take up poultry keeping for egg production, his choice of a breed is fairly limited. For all practical purposes there are only

[Papers Read at Conferences.]

two breeds of fowls worth considering, namely, the White Leghorn and Black Orpingtons or Australorps, as they are now more suitably known. I have tried out fairly extensively White Leghorns, Australorps, Rhode Island Reds, and in a more limited way Light Sussex, but in my opinion there is only one fowl, and that is the Australorp. Under certain conditions the White Leghorn may lay a few more eggs than the Australorp; for instance, when kept under intensive conditions, although the records of the leading egg-laying trials do not prove this.

It may meet the case to say that both breeds are excellent layers, and look for any difference in other directions. Where the Australorps have a definite lead is in their docility. A 6ft. netting placed about 9in. in the ground is sufficient to keep an Australorp within bounds, but I am not prepared to say what height is required to keep a Leghorn, for if the fence is too high for them to fly over, they climb up the netting and get over that way.

As 50 per cent. of the chickens hatched are cockerels, they have an important bearing on the rearing costs of chickens. In White Leghorns it is generally admitted that it pays best to destroy the cockerels as soon as the sex can be distinguished. On the other hand, I forwarded a crate of 24 Australorp cockerels to the Adelaide markets, in time for the Christmas market, which brought £6 4s. 10d., the highest birds bringing 5s. 7d. each. After deducting commission, rail, and cartage, the net proceeds were £5 1s. 4d., which must be considered highly satisfactory for five months old cockerels.

Having chosen the breed, the greatest care must be taken to see that a good strain of that breed is chosen—layers of full-sized eggs fit for export, anything else being a glut on the market. Having got suitable birds, feed and tend them well, for it can as truly be said of poultry as of larger stock, that half their breeding is what goes down their throat.

A block with a patch of orange trees, which can be conveniently fenced off for poultry is very suitable, for whilst the trees provide shade for the poultry, the droppings of the birds are of great benefit to the trees. It is not suggested that a man whose time is fully occupied with his block should take up poultry keeping, but it is worthy of serious consideration by those who have, perhaps, a family growing up and no apparent opening for them in life. I am fully convinced that nowhere can poultry keeping be more profitably undertaken than in conjunction with a Murray fruit block.

SOME ASPECTS OF VINEYARD MANURING.

[O. WESTE, Renmark.]

The subject of vineyard and orchard manuring is a very big one which covers a range difficult to deal with in a short paper, but it is a subject nevertheless about which the practical grower usually gropes in the dark, works by rule of thumb, and is liable to jump at hasty conclusions with results obtained. When we have plants to deal with where the bud and bunch determination is developed more than a year previous to harvesting it is necessary to cover many years' observations before arriving at any conclusions relative to manuring and its relationship to crop returns.

Those who have spent many years growing fruit have been through a phase of indecision regarding the need for organic matter during the early part of our experience. While the vines were young and vigorous, and still bearing good crops, we believed that the process would last indefinitely. But it will not. Just as soils vary in type, they vary in fertility, so that it will take some soils longer than others to lose their original fertility, and when crops begin to go back, we are forced to the conclusion that perhaps after all there is something more needed to produce successive payable crops than to simply irrigate and cultivate. In every producing country in the world growers have experienced the

[Papers Read at Conferences.]

exploitation of their rich soils and have learned the lesson of the fallacy of taking yearly crops without putting anything back in the way of organic matter. We find reference in Sir John Russell's book, "Soil Conditions and Plant Growth," as follows:—

"The crowding of population into cities, and enormous cheapening of transport rates, led during the nineteenth century to the adoption in new countries, particularly in North America, of what is perhaps the most wasteful method of farming known: continuous arable cultivation without periodical spells of leguminous and grass crops.

"The organic matter was rapidly oxidised away, leaching and erosion increased considerably when the cover of vegetation was removed, while the compound particles that had slowly been forming through the ages soon broke down. Nothing was returned to the soil, the grain and other portable products were sold, and the straw burned.

"The result has been a rate of exhaustion unparalleled in older countries, and wholly beyond the farmers' power to remedy, consequently he left the land and moved on."

Then again we find the same story in those exceptionally fertile Queensland sugarcane areas composed of alluvial volcanic soil which seemed inexhaustible, and after years of what is termed by Mr. R. A. Boyle as "mining" of the soils, necessary plant foods had to be applied to restore their lost fertility. And so it goes on from place to place until we come nearer home, and find that our shallow River soils in the course of time become exhausted, and yield unpayable crops, unless they are supplied with necessary chemical plant foods and organic matter.

Taking our River soils generally in these localities, on chemical analysis, they have shown themselves particularly low in phosphoric acid and nitrogen, and relatively high in potash. Mr. J. K. Taylor in Bulletin No. 42 of the C.S. & I.R. on "Soil Survey of Block 'E' and Chaffey Areas," in summarising the soil requirements said: "The inference is, that phosphatic and nitrogenous fertilisers are essential for maintaining and improving the fertility of both the good and poor types of soils, there is ample potash present, and the heavy applications of gypsum customary, would assist in the liberation of available potash."

VINE MANURING.

Owing to the indefinite and often contradictory nature of experiments in vine manuring, covering many countries, it seems necessary for each grower to be his own experimenter to a certain extent, keeping in mind the necessity for a proper balance of the three major soil requirements, viz., nitrogen, phosphoric acid, and potash.

To get some understanding of these three necessities we may quote Professor Perold, of the Stellenbosch University, in his book, "A Treatise on Viticulture," quoted as follows:—"Nitrogen promotes particularly the vine's vigour. A great development of shoots and leaves of a dark-green colour must be attributed especially to nitrogen. Weakened vines should therefore get a preponderating nitrogen dressing, whilst very vigorous vines that are not sufficiently productive require little or no nitrogen, but a heavy phosphate and potash dressing to render them productive.

"An excess nitrogen nutrition results in grapes that are rich in nitrogen, fairly soft and susceptible to disease, and with low keeping qualities. Wine made from such grapes is especially susceptible to bacterial disease. Vines that grow too vigorously owing to excessive or one-sided dressings of nitrogen are especially susceptible to all kinds of diseases and pests.

"Phosphoric acid helps to neutralise the evil effect of an excessive nitrogen dressing. It encourages the production of grapes and better setting of berries; it also promotes the better ripening of grapes and wood which takes place sooner and more completely, so that grapes at maturity will be sweeter than they would

[Papers Read at Conferences.]

otherwise have been. Hence we can say that it raises the quality of the grapes and wine.

"This accounts for the very heavy dressings of phosphates in the wine districts of France which produce wine of very high quality."

We also have another authority who makes a strong point with phosphoric acid in relation to wine making. Dr. Paul Wagner, of Dorumstadt, says:—"It is the phosphoric acid which forms the good wines, and regulates production by the prevention of coulure; it also makes wine more resistant to disease."

Professor Perold says of potash: "Potash plays an important part in the formation of carbohydrates, hence potash stands in the same relation to the carbohydrates as phosphoric acid stands to the proteins."

Considering our cultural practices in relationship to the balancing of our soils, I wonder if we pay due regard to the characteristics of our vines, to find out what is deficient and what is plentiful. For several years past our crops have been increasing—owing to better cultural practices—yet the quality of our currants has deteriorated. A possible explanation of this may be due to the fact that the growing of leguminous cover crops has increased the nitrogen content of the soil, without being adequately balanced by sufficient phosphates or perhaps potash.

An outstanding instance of a badly balanced soil came to my notice quite recently, when a Block "E" grower complained about his Sultanas drying at 900 tins to the ton, his currants being chiefly skin and water, without any body. Vines grew so rampant that he had difficulty in keeping them in check.

His method of treatment consisted of planting yearly cover crops of legumes, supplemented by dressing of about 3cwts. of sulphate of ammonia. He did not use sulphates because he believed that, as up to 10cwts. of superphosphate per acre had been applied at the Berri Experimental Orchard with negative results, this manure was not necessary.

[Papers Read at Conferences.]

In this instance there appears to be an excess of nitrogen, and taking into consideration the low phosphate content of our soils generally, there seems to be a very great need for heavy dressings of phosphates to create a balance in this case.

In his book on "Fertilisers for the Orchard and Garden," Mr. R. A. Boyle says:—"The mere act of replenishing one element may cause another automatically to become deficient. For example, there may be a shortage of nitrogen in a certain soil, but as a result of increased growth, due to added nitrogen, there may be insufficient phosphate to maintain this extra growth and so a phosphate deficiency results. The application of nitrogen and phosphate may, in turn, expose a relative scarcity of potash when only with a mixed fertiliser having nitrogen, phosphate, and potash content suitably balanced to suit all conditions, may efficient production be attained."

Although our soils show a comparatively high potash content which can be made available by applications of gypsum, we are not sure whether enough is available to balance the heavier dressings of both sulphate of ammonia and phosphates applied in recent years by many growers.

COVER CROPS.

By far the most important soil requirement in our arid regions is organic matter, for only by the aid of organic matter can we increase its bacterial activity. My practice in this respect is to plant every other row with peas and every other row with beans, so that every row of vines carries a cover crop.

Peas are usually ready to plough under in July and the beans are matured by September. I find no difficulty in ploughing the currant cuttings in with the peas by throwing them on top of the growing crop, but the peas in sultana rows are ploughed in before pruning, and prunings placed in a deep furrow down the centre of the row. All this helps to make organic matter, and it is pleasing to note the gradual spread of this practice in the last few years, first advocated by Mr. Vaillaire.

It is almost impossible to lay down a hard and fast rule for orchard manuring, but the least we can do is to consider the applications and methods of those who have increased their tonnages by the following treatment. When planting leguminous cover crops, apply 2 to 3cwts. super with the seed, supplementing this with a further dressing of super before bud burst, to make the total yearly amount up to 4 to 5cwts. per acre for every ton of dried fruit harvested. At first sight, this might appear excessive and above the absorbing capacity of the vine, nevertheless this has met with such success that it cannot be ignored.

In the event of cover crops maturing later in the season—in which case the breaking down and nitrification may be incomplete by the time the new season's rootlets are seeking nutriment—it would be necessary to give a dressing of artificial nitrogen, always keeping in mind the need for keeping a soil balanced with the major requirements: nitrogen, phosphate, and potash. Although there are many other minor requirements to balance a soil, these are generally in sufficient quantity to cause us no trouble.

Among the so-called minor requirements is sulphur, but as experiments are now in progress in these areas by the Waite Institute, it may be some little time before definite data is made available, but having isolated the bacteria which converts the sulphur into sulphuric acid, these experiments have already proved encouraging enough to proceed upon practical lines.

Experiments which have been carried out at the Merbein Experimental Station under Mr. A. V. Lyon have shown the influence on the size of bunch and quality of the fruit relative to the size of the cane, and as the size of the cane depends entirely on the amount of nutriment the vine gets between bud burst and setting time, it is of the utmost importance to get all manures in place before bud burst, ~~that we~~ ^{then we} can be assured of the vine getting the maximum benefit from our efforts.

ANNUAL WINTER SCHOOL FOR FARMERS, 1934.

The Annual Winter School for Farmers will be held at Roseworthy Agricultural College from the morning of August 8th to the morning of August 17th. In the following curriculum, which has been arranged for the School, the morning sessions, unless otherwise indicated, will be devoted to lectures, the afternoon sessions to outdoor demonstrations conducted on the Farm and accompanied by lecturettes on the subject, while the evening sessions will be devoted as far as possible to illustrated lectures of a general nature.

Conditions for enrolment have been circularised to all Branches of the Agricultural Bureau; non-members of the Bureau are eligible to join the School, and will be supplied with particulars on application.

Rural producers living in the environs of the College are cordially invited to attend any or all of these lectures or demonstrations. Meals can be obtained at 1s. 6d. each, provided the Housemaster is advised a short time beforehand.

CURRICULUM.

Wednesday, August 8th.

10.30 a.m.	Opening of the School	Hon. A. P. Blesing (Minister of Agriculture)
1 to 4 p.m.	Inspection of College Farm	Mr. O. Bowden
7.30 p.m.	Export Markets and their Requirements	Mr. C. F. McCann (S.A. Trades Commissioner in London)

Thursday, August 9th.

8 to 9.30 a.m.	The Care of the Cow on the Farm	Mr. R. Baker
10 to 11.30 a.m.	Cereal Varieties and where to grow them ..	Mr. R. C. Scott
1 to 4 p.m.	Conformation in Relation to Utility in Horses	Mr. C. T. McKenna and Mr. R. Nott
7.30 p.m.	Petroleum from Well to You (a Talkie)	Mr. B. V. Crewe

Friday, August 10th.

8 to 9.30 a.m.	Rotational Systems and Livestock Relationships	Dr. A. R. Callaghan
10 to 11.30 a.m.	Breeding Wheats for the Farmer	Mr. E. J. Breakwell
1 to 4 p.m.	Ensilage on the Farm ?	Dr. A. R. Callaghan and Mr. O. Bowden
7.30 p.m.	Measuring Soil Fertility	Mr. J. K. Taylor

Saturday, August 11th.

8 to 10 a.m.	Pruning Demonstration, Vines and Fruit Trees	Mr. J. L. Williams
-------------------	--	--------------------

Monday, August 13th.

10 to 11.30 a.m.	Chemistry in Agriculture	Mr. A. R. Hickinbotham
1 to 4 p.m.	Wool Classing and its Importance to the Small Grower	Mr. A. H. Codrington
7.30 p.m.	Factors Affecting the Production of Wheat ..	Prof. A. E. V. Richardson

Tuesday, August 14th.

8 to 9.30 a.m.	Poultry Keeping as a Farm Sideline	Mr. F. W. Gilbert
10 to 11.30 a.m.	Conformation in Relation to Utility in Dairy Cattle	Mr. H. B. Barlow
1 to 4 p.m.	Agricultural Machinery and its Repair	Mr. A. J. A. Koch and Mr. H. R. Nourse
7.30 p.m.	Pasture Development in South Australia	Mr. H. C. Trumble

Wednesday, August 15th.

8 to 9.30 a.m.	Costs in Relation to Farm Records	Mr. W. H. Cowper

IMPORTANT WEEDS OF SOUTH AUSTRALIA.

[By G. H. CLARKE, B.Sc., Botanist at the Roseworthy Agricultural College.]

No. 7.—NUT-GRASS.

Cyperus rotundus, L.

Nut-grass is a weed of home gardens, public parks, market gardens, and other situations where rich soil and abundant water supply combine in offering conditions especially favourable to the growth of this plant. Strictly speaking, it is not a grass at all, but belongs to the closely related family of sedges, which differ from true grasses in a number of important characters. Strangely enough, Nut-grass is a native of Australia as well as of most other temperate and tropical countries of the world. It grows in Central Australia and in the Northern parts of this State, forming part of the native vegetation of those areas; but in the South, where it is most troublesome as a weed, it is probably an introduction. So far the true Nut-grass does not appear to be a serious pest of wheat land, or even of pastures, in this State, except in a few situations. But certain grass-like members of the Iris family (*Iridaceae*) are sometimes mistaken for Nut-grass, and to these, in certain districts, the name is wrongly applied. Such, for example, are the two species of "Onion-grass," namely, *Romulea rosea*, Eckl., and *Romulea columnae*, S. et M., and an extremely common one-leaved variety of *Moraea xerospatha*, MacO. All three have narrow grass-like leaves, and each produces a tough underground bulb-like enlargement termed a corm. These corms are sometimes mistaken for the so-called "nuts" or tubers of the true Nut-grass, formed as localised swellings of the underground stems or rhizomes. These Iridaceous plants may be readily distinguished from *Cyperus rotundus* by their flowers which, though few in number, are relatively large and conspicuously coloured, violet or blue, whereas the flowers of *Cyperus* are more like those of true grasses, that is to say, they are small and inconspicuous, and are grouped together in slender cone-like inflorescences termed spikelets.

Botanical Names.—*Cyperus* is the Latin form of *kuperos*, or *kypeiros*, names applied by the Greeks to some species of sedge; *rotundus* means "round," and is in allusion to the rounded tubers or swellings of the underground stems.

The Sedge Family.—The *Cyperaceae* or Sedge family comprises nearly three thousand species of grass-like herbs inhabiting chiefly marshy situations in most parts of the world. They are mostly perennials with either tufted or creeping underground stems which terminate in solid, often angular, aerial stems with two or three ranks of long narrow leaves. The plants are of coarser texture than grasses, from which they differ also in having the sheathing bases of the leaves entire instead of being split lengthwise on the side away from the blade, and the stems solid and uniform, and sometimes compressed or angular, instead of hollow and swollen at the nodes, as is usual among grasses. Apart from these differences, and certain others in the structural details of the flowers and spikelets, the grasses and sedges together form a very natural group of plants. They resemble each other closely in general habit, notwithstanding the differences mentioned; but it is in the structure and arrangement of the flowers that the close relationship between the two families is most clearly revealed.

By the term "inflorescence" is meant an arrangement of flowers, and in most cases it is one of single flowers. In short, the unit of an inflorescence is usually a single flower. But in grasses and sedges the units are not single flowers but spikelets: that is, they are minor inflorescences made up of one, two, or more flowers borne on a slender axis together with protecting bracts, arranged

so as to form compact structures. The individual flowers are small and wind-pollinated. Each is situated in the axil of a bract called a glume, there being usually two or more empty glumes at the base of each spikelet. In both grasses and sedges the spikelets may be arranged in a great variety of different ways so as to form major inflorescences of many different kinds.

The Genus.—*Cyperus* is a large genus and comprises about four hundred species distributed throughout the tropical and subtropical regions of the world, the species becoming less numerous in temperate zones. It is distinguished from other genera of sedges by having spikelets with numerous bisexual flowers arranged in two opposite rows together with the subtending glumes, the spikelets themselves being grouped in heads or umbels with an involucre of leafy bracts at the base. The involucre bracts are sometimes long, on which account certain species, grown for ornament, are often referred to as "Umbrella-grasses" or "Umbrella-sedges."

One species, *Cyperus papyrus*, L., was the source of the papyrus or writing paper of the Egyptians, the stems being cut into thin strips and pressed together while still wet. Of the sixty-five species in Australia, some nineteen occur in this State, and from these *C. rotundus* is distinguished by the umbellate arrangement of the spikelets, the axes of which are winged, due to the persistent bases of the glumes, the three-cleft styles of the flowers, the slender aerial stems three-angled above, and by the extensive system of underground stems swollen here and there into rounded tubers.

Description of Cyperus rotundus.—Rhizome creeping or stoloniferous, swelling here and there into tunicated tubers, the scales when worn away leaving annular scars or zones. Stems rather slender, usually 1 to 1½ feet high, but sometimes short, triquetrous towards the top. Leaves rather narrow, much shorter than the stem, the sheaths often long and loose. Spikelets usually 6 to 10 together in clusters or short spikes in an umbel of few rays, the outer ones sometimes slender and 2 or 3 inches long but more frequently the umbel rather dense and sometimes almost contracted into a compound cluster. Involucre bracts few, 1 or 2 longer than the inflorescence. Spikelets usually of a rich brown, linear, acute, compressed but not very flat, usually about ½ inch long and rather more than one-twelfth inch broad, with 12 to 20 flowers, but varying to a much greater length, the rhachis slightly flexuose and bordered by rather broad hyaline wings either persistent or at length deciduous. Glumes imbricate, not very broad, obtuse or rather acute, more or less distinctly several-nerved, with a prominent keel usually green. Stamens 3. Style 3-cleft. Nut obovoid, 3-angled, less than half the length of the glume. Period of flowering: December-May.

Properties.—Though not poisonous, Nut-grass is not of much value as food for stock owing to the toughness of its aerial parts, but stock are said to eat it readily enough, more particularly the tubers, which are said to be greatly relished by pigs. The tubers are edible, and have been used as human food by the aborigines in various parts of Australia.

The plant owes its reputation as a weed to a very deep-rooted habit and an extraordinary tenacity of life, which makes it one of the most difficult weeds to exterminate. Given favourable conditions, the roots extend down to considerable depths in the soil. A case is on record where they were reported to be 30 feet below the surface of the ground. The roots and underground stems may be so dense as to choke out other plants; they may penetrate the roots and tubers of other plants, and may push their way through asphalt. Hoeing and cultivation are not of much use as methods of eradication since new aerial shoots are formed by the tubers and fragments left behind in the soil.

Eradication.—It is not an easy task to get rid of Nut-grass, though its spread can be greatly retarded by preventing the maturing of seed above ground. The treatment should aim, firstly, to prevent seeding, and, secondly, to exhaust the underground parts. The growth of the aerial shoots takes place, in the first instance, at the expense of food reserves stored in the tubers; during the later stages of growth, however, the passage of food substances is in the reverse direction, new tubers being formed underground to store the surplus food built up by

Nutgrass. Photograph of single plant showing the general habit (see coloured plate opposite).

NUT GRASS (*Cyperus rotundus* L.)

A.—Spikelet. B.—Transverse section of flowering stem. C.—Transverse section of leaf.
D.—Spikelet-scale. E.—Fruit not fully ripe. F.—Transverse section of fruit. (All enlarged).

the leaves. Hence it is a matter of great importance to attack the weed during its early stages of growth, before the seeds have developed. During the early summer the aerial parts should be destroyed, and, by frequent stirring of the ground, the tubers should be stimulated to produce as many new shoots as possible. These in turn should be destroyed before they have had a chance to form seed, the process being repeated as often as is necessary. By such means the underground parts are debilitated and, if not actually killed, are at any rate rendered less capable of producing a vigorous growth the following year. After such treatment a thick sowing of some suitable winter crop may succeed in choking out the Nut-grass.

The use of chemical sprays such as arsenite of soda or sodium chlorate is not recommended except on garden paths, &c., where residual effect does not seriously matter. Repeated applications are necessary to ensure successful results.

In garden beds it is seldom possible to get rid of the weed by digging or hoeing unless great industry and perseverance are shown and due regard is paid to the principles mentioned. A method which has been used successfully is to cover the affected ground with manure to a depth of a foot or more and leave it for a couple of years. By this means light is excluded and the fermentation process helps to prevent the growth of the weed below it.

(The writer's thanks are due to Miss C. M. Eardley, B.Sc., of the Waite Agricultural Research Institute, for supplying material from which the accompanying illustrations were prepared.)

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

CHAMPIONSHIP PRUNING COMPETITIONS.—RIVER MURRAY.

The Championships of the Annual Pruning Competitions arranged for Branches of the Agricultural Bureau situated along the River Murray were held in the Government Experimental Orchard, Berri, on Thursday, July 5th.

RESULTS.

Judges: Messrs. E. Leishman and F. R. Arndt (Department of Agriculture) and L. Chapple.

TREE SECTION.

Competitor.	Branch.	Apricot.	Peach.	Pear.	Total.
A. Wedd	Mypolonga	86	92	87	265
W. Harris	Berri	86	87	87	260

Trophies were donated by the Royal Agricultural and Horticultural Society, Dried Fruits Board, Adelaide Chemical Co., and Wallaroo-Mt. Lyell Fertilizer Co.

The Judges—Messrs L. Chapple, E. Leishman and F. E. Arndt.

LANGDON PARSONS'S TROPHY.

This trophy was donated in 1933 by Mr. H. Langdon Parsons, and is to be awarded to the competitor in local competitions who secures the highest aggregate points over the three years 1933, 1934, and 1935. Last year the trophy was held by Mr. E. A. Liddicoat, of Moorook. This year Mr. H. M. Perkins, of Berri will hold the cup.

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

RIVER MURRAY CONFERENCE.

The River Murray Conference was held at Barmera this year on June 22nd, and attracted a large number of members from Moorook, Rameo, Waikerie, Barmera, Cobdogla, Monash, Berri, Renmark, and Block E.

Mr. H. B. Williams presided, and there were also present:—Messrs. J. B. Murdoch (Advisory Board of Agriculture), Professor Perkins (Director of Agriculture), Geo. Quinn, R. Fowler, N. S. Fotheringham, F. R. Arndt, and H. H. Orchard (of the Horticultural Branch), C. F. Anderson (Poultry Expert), H. C. Pritchard (General Secretary) and J. K. Taylor (Council of Scientific and Industrial Research). Mr. O. W. Till acted as Local Secretary.

An attractive display of wines was tabled by the Berri Distillery, and trade boxes of sultanas and oranges were exhibited by the Barmera Co-operative Packing Company.

Mr. J. B. Murdoch delivered the opening address.

Papers were read by Mr. O. Weste (Renmark), "Vineyard Manuring"; Mr. N. S. Fotheringham (Berri), "Insect Pests in Irrigated Areas"; Mr. F. R. Arndt, "Review of the 1934 Drying Season"; and Mr. W. McGillivray (Barmera), "Poultry Keeping." Messrs. W. R. Lewis, F. R. Arndt, and N. S. Fotheringham reported on "the conditions and results of the sultana vine in connection with the six years' pruning," and in the evening Mr. J. K. Taylor addressed the Conference on "Progress of Irrigation Research in the Horticultural Areas of the River Murray," with special reference to soil problems.

The following resolutions were carried:—

"That legislation be passed compelling vendors of dusts as fungicides or germicides to brand the bags with both the analysis and the trueness of the contents."

"That the egg industry be placed on a business-like footing, and that the Government create an egg pool."

"That the next Conference be held at Moorook."

EYRE'S PENINSULA (WEST) CONFERENCE.

The Mudamuckla Branch was responsible for the Ceduna Conference this year on July 4th. The Conference was well attended by members of neighbouring Branches, and the proceedings were formally opened by Mr. P. J. Bailly, of the Advisory Board of Agriculture. Mr. W. H. Watson presided, and there were also present:—Miss E. Campbell (Education Department), Professor Perkins, Messrs. H. B. Barlow (Chief Dairy Instructor), C. F. Anderson (Poultry Expert), A. H. Robin (Stock and Brands Department), W. H. Brownrigg (Agricultural Instructor), and H. C. Pritchard (General Secretary). Mr. A. R. Maguire undertook the duties of Local Secretary.

Papers were read by Mr. J. W. Blumson (Laura Bay) on "Wheat Growing in County Way"; Mr. C. W. Bergmann (O'Loughlin), "Wheats Best Suited to the District"; Mr. A. C. Watson (Mudamuckla), "Operations on the Farm from Seeding to Seeding"; Mr. A. R. Maguire, "Sheep on the Farm"; Mr. L. B. Hughes (Goode), "Rabbit Destruction"; Mr. E. Morcombe, "Social Side of Farm Life"; Mr. C. Halahan, "Bookkeeping on the Farm"; and Mr. T. R. Zippell (Mudamuckla), "The Vegetable Garden."

Resolutions were carried as follows:—

"That the next Conference be held at Ceduna, under the auspices of the Goode Branch."

"That Parliament continue to permit the Agricultural Department to issue delegates with free fares to attend the Adelaide Congress meetings."

"That the wild dog tax be written off."

"That members for the district be asked to move for a reduction in the motor tax and drivers' licence."

“That the registration of bulls be abolished in County Way.”

“That more information be given in the rainfall tables published in the *Journal*.”

During the lunch adjournment a visit was made to the new butter factory, and in the afternoon Mr. Barlow addressed the meeting on “Dairy Cattle Suitable for the District.” The evening session was devoted to replies by Mr. Robin to numerous questions dealing with ailments of livestock.

WOMEN'S SESSION.

This was the first occasion on which a Conference of members of Women's Branches has been held on the western portion of Eyre's Peninsula. The attendance was much greater than was anticipated. Mrs. D. F. Morrison (Laura Bay) presided, and papers were submitted by Mrs. W. Pfeiffer (O'Loughlin) on “Jam Making”; Miss L. Kloeden (O'Loughlin), “The Uses of Cold Meats”; Mrs. W. E. Bowell (Laura Bay), “The Danger of Flies in the Home”; Mrs. D. Fagan (Goode), “Soup Making”; and Miss R. E. Blumson (Laura Bay), “Dairying.” Miss E. Campbell gave an address and demonstration on “The Uses of Hessian in the Home.”

Messrs. P. J. Baily, H. B. Barlow, C. F. Anderson, and W. H. Brownrigg attended the Women's Conference at various times to discuss dairying and poultry subjects.

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board was held on Wednesday, June 27th, there being present Messrs. A. J. Cooke (Chairman), H. N. Wicks, A. L. McEwin, P. J. Baily, Geo. Jeffrey, F. Coleman, A. M. Dawkins, Prof. A. E. V. Richardson, Prof. A. J. Perkins, and H. C. Pritchard (Secretary). An apology was received from Mr. A. J. A. Koch.

Trade Commissioner.—Mr. C. F. G. McCann (Trade Commissioner), attended the meeting at the invitation of the Board, and gave a comprehensive description of the market prospects for Australian produce in England, and of the manner in which our produce was sold overseas.

Conferences.—The Secretary reported that Conferences would be held at Wilmington on July 18th and Karoonda on July 31st.

New Branches.—Conditional approval was given to the formation of Women's Branches at Truro and Monarto South.

Life Member.—Mr. W. A. Crossman (Wareowie) was approved as a Life Member of the Agricultural Bureau.

New Members.—The following names were added to the rolls of existing Branches:—Bute—W. N. Trengrove, A. J. Drewett, Mervyn Green, Eric R. Paterson, J. A. Trengrove, Ralph Trengrove, Colin O'Loughlin, Eric J. Commons, C. R. Warren, Michael Devitt, Wendt Sluggett, Harold E. W. Sluggett, E. J. Axford; Monarto South—E. Rolland; Yandiah—Clarence Giddings; Warrambo Women's—Miss C. N. Chilman; number of new Members, 18; present number of Members, 7,865; present number of Branches, 337.

Retirement of Members.—In accordance with the constitution of the Board the following members retired on June 30th:—Messrs. F. Coleman, A. M. Dawkins, H. N. Wicks, A. J. Cooke, P. J. Baily. All were eligible for re-appointment by the Honourable Minister.

Several items were discussed in Committee.

DAIRY AND FARM PRODUCE MARKETS.

Messrs. A. W. SANDFORD & Co., LIMITED, reported on July 2nd, 1934:—

BUTTER.—Values for butter in the local market have continued on an even keel throughout June, but the production has been very disappointing. Unfortunately, good general rains have not yet fallen, and therefore the country, generally speaking, is in very backward condition, and in most parts hand feeding of stock is necessary. Some few tons of butter have been exported from week to week, but this was only of first and second grade, all the choicest produced being required for local trade. London market is still ruling at low prices, from 71s. to 82s. per cwt. There has not been anything decided in regard to whether this State will go into the "All Australia Plan," but some action will be necessary soon after Parliament meets. Present quotations are:—Choicest creamery fresh butter, in bulk, 1s. 3½d. per pound. Prints and delivery extra (these prices are subject to stabilization levies). Store and collectors' lots, 6½d. to 7½d. per pound at store door, according to quality.

CHEESE.—Advices from the South-Eastern factories indicate that the supplies of milk are now increasing and consequently cheese consignments are showing better tonnage each week. Values showed some improvement towards the latter end of June, and at present the range is:—Large and medium, 8½d. to 8¾d. per pound; loaf, 8¾d. to 9½d. per pound; semi-matured and matured, 8½d. to 9½d. per pound.

EGGS.—Supplies are now increasing each week and some of the packing floors have commenced grading and packing for export. However, it is yet early for large quantities to go forward, and the maximum shipments are not usually sent forward until October or November. However, values are maintaining well for this season of the year, and the outlook for a satisfactory season seems bright. Values are as follows:—Ordinary country eggs, hen or duck, 8d. per dozen; selected fresh eggs, of export quality, 1½ozs. and over, 9d. to 10d. per dozen.

BACON.—The turnover in bacon throughout the month of June was well maintained, but this was only to be expected as the consumption of bacon is usually much greater than in the hotter months of the year. Factories marketed, from week to week, quantities necessary to meet trade requirements and values have continued steady. Best quality sides, 9½d. to 9¾d.; middles, 10½d. to 11d.; rolls, 8d. to 8½d.; hams, 11d. to 11½d.; cooked, 1s. 2d. to 1s. 2½d. per pound; lard prints, 6½d. per pound.

ALMONDS.—Only limited quantities of almonds were sent forward to the open markets, but these were readily cleared from week to week at quotations. Most of the shell lines were purchased by crackers, and as the kernels were required for both local and interstate trade there was an excellent demand ruling throughout and rates were satisfactory. Softshells and Brandis, 8½d. to 9d. per pound; hardshells, 5½d. per pound; kernels, 1s. 11d. to 2s. per pound.

HONEY.—Sales of honey continued somewhat slow as the orders from interstate buyers were disappointing. Local buyers purchased from week to week, but very few sales of parcel lots were negotiated. Values continued steady. Prime quality clear extracted in liquid condition, 3½d. to 4d. per pound; lower grades, 2d. to 2½d. per pound.

BEESWAX.—Ready sales were made of all consignments sent forward to the open markets and quotations remained without any alteration. 1s. 4d. to 1s. 4½d. per pound, according to quality.

LIVE POULTRY.—Sales are held every Tuesday, Thursday, and Friday, and our sale rooms are the best equipped in the State. Large attendances of buyers were recorded at each of our sales, and representative catalogues were submitted. Values for some classes were well maintained but poor quality sorts fluctuated somewhat. We advise consigning. Crates loaned on application. Prices were as follows —Prime roosters, 3s. 4d. to 4s. 3d.; nice conditioned cockerels, 2s. 9d. to 3s. 3d.; fair conditioned cockerels, 2s. 3d. to 2s. 8d.; chickens, lower; heavyweight hens, 2s. 4d. to 3s. 1d.; medium hens, 1s. 9d. to 2s. 3d.; light hens, 1s. 6d. to 1s. 8d.; couple of pens of weedy sorts, lower; prime young Muscovy drakes, 3s. 3d. to 4s. 3d.; young Muscovy ducks, 2s. 3d. to 2s. 10d.; ordinary ducks, 1s. 6d. to 2s. 4d.; ducklings, lower; geese, 2s. to 3s.; goslings, lower; turkeys, good to prime condition, 8½d. to 11d. per pound live weight; turkeys, fair condition, 6½d. to 8d. per pound live weight; turkeys, poor and crooked breasted, lower; pigeons, 5d. to 5½d. each.

POTATOES.—New season's, 9s. per cwt.

ONIONS.—Brown Spanish, 6s. 6d. per cwt.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[The new Bureau subscription rate of 2s. per annum, which was recommended at the 1933 Congress, applies to all members as from August 1st, 1934, with the following exceptions:—Life Members, Branch Secretaries, and members who reside in the same house as (a) a Life Member, or (b) a Branch Secretary, or (c) a subscribing member. Subject to the foregoing exceptions, new members joining during the months of July to December will pay 2s. per annum, and those joining during the months of January to June 1s. for that period and 2s. for each succeeding year. Subscriptions must accompany the nomination forms unless the nominee is exempt.]

MEN'S BRANCHES.

SUBJECTS DISCUSSED AT BUREAU MEETINGS.

If you have no other subject in mind, here is a list from which you might choose when asked to contribute to your branch programme. The list has been compiled from published branch reports.

Agriculture.	Horticulture.	Livestock.	General.
Barley Growing. Harvest Reports. Pasture Management. Fallowing. Care of Machinery. Control of Drift. Fodder Crops. Haymaking. Crop Rotation. Seeding Operations. Wheat Pickling. Wheat Diseases. Wheat Varieties for the District. Seed Wheat. Value of the Oat Crop. Wheats for Milling. Peas. Wheat v. Sheep. Wheat Varieties for Hay. Crop Competitions. Harvest Operations. Value of Agricultural Experiments. Cultivation. Fertilisers and Manures. Cultivator v. Plough for Fallowing. Tobacco Culture. Meadow Hay. Review of the Past Season.	Cincturing. Spraying. Pruning. Orchard and Garden Pests. Fruit Drying. Drainage. Potatoes. Tomato Culture. Vegetable Growing. Citrus Culture. Packing and Grading Fruit. Budding and Grafting. Orchard Cultivation. Rack Building. Fruit Preserving. Irrigation. Seepage. Care of Orchard Equipment. Farm Garden. Diseases of the Vine. Manures for the Orchard. Fruit Tree Diseases. Planting the Orchard. Frost Prevention. Fumigation for Scale Insects.	Calf Rearing. Care of Farm Livestock. Management of Horses. The Brood Mare. Colt Breaking. Shoeing Horses. Sore Shoulders. Weaning Foals. Lamb Marking. Sheep Management. Wool Classing. Shearing. Sheep Dipping. Fat Lambs. Handfeeding Sheep. Poultry. Shelter for Livestock. Management of the Dairy Cow. Care of the Breeding Ewe. Pigbreeding and Management. RENDELSHAM.

May 26th.—Attendance, 14.

QUESTION BOX.—The following questions and answers resulted from the Question Box:—"When is the best time to set eggs of White Leghorns for hatching?"—*Ans.*: August and September. "If a rooster is running with a flock of hens will they lay more or less eggs?"—*Ans.*: Hens will lay as well without as with a rooster. "What is the best method to get ducks to start laying?"—*Ans.*: Feed and treatment will give best results, especially if a good plot of greenfeed is available for the birds. The best feed is a mash of bran and pollard with meal with meatmeal in the morning and grain feed at night. "Do fowls pay with eggs at 6d. per dozen?"—*Ans.*: Yes; a profit can be shown with eggs at 5d. a dozen. "Does top-dressing of pastures pay?"—*Ans.*: Yes; if super is used at about 1cwt. to the acre, especially for the grazing of sheep. "How long after the seeding of rape before it can be fed off?"—*Ans.*: No definite time can be stated, as it depends on the growth of the crop, but as soon as it is well-rooted it can be fed off—usually from about six weeks to two months after seeding. (Secretary, F. White.)

NOXIOUS WEEDS.

(A Paper read by Mr. E. S. Alcock (District Agricultural Instructor) at the June meeting of the Mount Gambier Branch.)

"The need for controlling the spreading of various plants was realised early in the State's history, for we find that legislation was passed by Parliament over 60 years ago to deal with this matter. Reports I have heard from time to time lead me to suspect that this Act was more rigidly enforced than it is to-day. In 1896 Mr. Albert Molineaux, founder of the Agricultural Bureau in South Australia, wrote pointing out the need for more elastic legislation. The various Acts were amended in 1931, and at the same time power was given for any plant to be proclaimed a noxious weed either throughout the whole State or any portion of the State, and to remove any plant from the schedule, provided special circumstances demanded it."

Mr. Alcock then read a list of the Proclaimed Weeds of the State:—

"In the Corporation area the following have been declared noxious:—*Fennell* and *Milk Thistle*.

African Boxthorn is a noxious weed for the whole State, except where grown as a hedge and kept trimmed to a width not exceeding 4ft., and not exceeding 7ft. high. A visitor in this district would hardly think in some years that we had a Noxious Weeds Act. In many places noxious weeds are allowed to grow unchecked. This is largely due to the lack of interest and knowledge by landholders and those who have the handling of the Act. This can be readily proved by anybody visiting the Tatiara District Council area, for they have a very efficient Council inspector in Mr. H. C. Williams, who has created quite a weed sense among the landholders in his district. He is doing a good job, and the same can be done in other centres by the co-operation of both landholders and council inspectors.

WEEDS IN THIS LOCALITY.

The weeds found in and around this locality are Wild Onion, Hemlock or Carrot Fern, Horehound, Boxthorn, Fennell, Milk or Variegated Thistle. Fortunately Wild Onion is not very prevalent; it has been kept well under control. No animal will eat it, although it will take possession if left unchecked.

Hemlock or *Carrot Fern* is a biennial plant, probably introduced by gardeners. It is similar to Fennell, but since it is poisonous, care should be taken to eradicate it as soon as possible. *Horehound*, a perennial plant, is another garden escapee which has recently been declared a noxious weed, since it is spreading on roadsides, gradually taking possession and displacing better type of plants.

Fennell:—A perennial plant which is a very strong grower, usually on roadsides. Along the Penola and other roads this is growing so strongly that it is dangerous to traffic and difficult for stockmen to move their stock in consequence of it. Steps should be taken to have this checked.

Milk Thistle or *Variegated Thistle*.—An annual plant, but an old offender in this district, for it is found growing strongly on roadsides and also in paddocks, displacing better plants.

Boxthorn.—This perennial plant is well known, for it was apparently one of the first plants used for a hedge in many places because of its hardness. In this district many miles have been destroyed from time to time, and there are still many miles which could be destroyed. The plant produces red berries, which are readily eaten by various birds. The seeds are thus distributed, and since it grows

rapidly it soon takes possession of vacant blocks and waste land. This plant can quite easily be replaced by many better plants, which are not so troublesome to keep in check. This is one plant with which more care could be taken to see that land-holders comply with the Act by those whose duty it is to enforce it.

Blueroot is a perennial plant which comes from Europe and Western Asia, probably a garden escapee, or it may have been imported with grass seeds. This plant may be useful to the grazier, but it is not very desirable among cultivated crops.

Bindweed.—This is a perennial deep-rooting plant, and is one of the worst weeds in this State. Sections have been taken from 4ft. below the surface, and these grow as well as those near the surface. It spreads by underground roots and seeds, and the only known means of checking such weeds as these is by the use of sodium chlorate.

Besides these weeds one might include such trees as White Poplars and Cork Elms. Unfortunately these were planted around the Leg of Mutton Lake and Hospital, and to-day they are overrun with their suckers, which present anything but a pleasant sight.

OTHER NOXIOUS WEEDS.

A few brief notes on the other weeds listed as noxious may be of interest here.

Cotton Bushes.—These are importations from South Africa, and grow on fertile soils in tall shrubs. The seed vessels of one are used for table decorations.

Woolly Star or *Star Thistle*.—Rather a tall, slender plant, not readily eaten by stock except when very young. A purple-flowered variety grows around Naracoorte. *Innocent Weed* has only been reported along the River Murray areas, and is not likely to thrive in this district. *Purple Star* or *True Star Thistle* is well-known to those who have travelled the Penola-Naracoorte Road, where it is growing profusely. *Yellow Cockspur* resembles *Saffron Thistle*, but is much stronger in growth and not readily eaten by stock. *Canada Thistle*.—This weed was at one time growing on the Glencoe Road, about 6 miles out, but it has now been destroyed. It spreads by underground stems, and is very difficult to deal with when once established. *Dodder*.—This is a parasitic plant, which lives on lucerne and other plants. To-day most lucerne seed is carefully cleaned so that this bad weed is rarely seen. *Thorn Apple* and *Apple of Sodom* grow with rather long leaves, carrying spines, and the look of them is generally sufficient to destroy them on sight. *False Caper*.—A sturdy annual plant belonging to the Spurge family. Most of these plants are poisonous and emit a milky fluid when broken. This grows well on sandy places, although, not readily eaten by stock, but should be suppressed when noticed.

Cape Tulip.—Two plants are listed under the name, one having one leaf and the other two leaves. This weed can also be seen between Kingston and Robe, and during September, when in flower, it presents a fine sight. Both plants spread rapidly by bulbs and seeds, and since they are poisonous and difficult to eradicate they should be carefully watched. The greatest danger with this, like many others, is that they are planted in gardens from which they escape and soon spoil good grazing areas.

St. John's Wort is another poisonous and dangerous weed, difficult to eradicate when once established. It produces underground stems, with roots as deep as 4ft. If you attempt to pull it up it breaks off, and each small root sends up a fresh stem. A small area appeared near Millicent a few years ago, but they got it under control by attacking it early. Another small patch appeared in the Penola railway yard, but this is also kept under by frequent attention. It has a rather pretty yellow flower and is perennial, growing erect about 2ft. high. *Californian Burr* and *Bathurst Burr* are two weeds which prefer warm districts. *Dyer's Weed*.—This is fairly common between Robe and Naracoorte. It can easily be distinguished, since it belongs to the mignonette family. It was once cultivated for yellow dye; hence the name. Stock will not eat it.

CONTROL OF WEEDS.

The most important point with regard to these seeds is to take care that you do not introduce them into your fields. Care should be exercised in the purchase of seeds, and to see that they are free from foreign weed seeds. Also, when purchasing fruit trees and garden plants examine carefully the earth adhering to their roots and see that they do not contain bulbs or roots of such weeds as sour sobs, hoary cress, etc. Stock can also spread bad weeds if they have been grazing where they are growing.

Once you have noticed a strange plant have it identified, and find out if it is likely to become a weed, because eradication is very often difficult, and may prove expensive if not checked in the early stages. Good cultivation will suppress many of these bad weeds, combined with heavy stocking. Others may be crowded out by sowing various pasture plants, but where these methods fail or are not applicable the use of some weedicide, such as sodium chlorate, may be used.

Care should be exercised to see that your purchase *sodium chlorate*, not *sodium chloride*, which is ordinary common salt. Sodium chlorate can be purchased at about 8d. or 9d. per lb. Used at the rate of 1lb. of sodium chlorate to 1gall. of water,

and sprayed on to the foliage with an ordinary spray pump, care being taken to see that all the foliage is thoroughly wet, this is very effective. This process is best done late in the spring on a dry day. When the vegetation is well established it may be necessary to repeat a number of times, but if persisted with this chemical will destroy any vegetation. Care should also be taken in using sodium chlorate to see that clothes and other vessels, vehicles, &c., which have been used in connection with the spraying of this chemical are carefully washed after. Otherwise, if the solution is allowed to dry on the operator's clothes or other articles they may catch fire at a later date, for it is very inflammable when mixed with organic matter. There is no danger provided these precautions are taken, since sodium chlorate is readily soluble in water."

APILLA (Average annual rainfall, 14.6in.).

June 1st.—Attendance, 12.

GREENFEED AND ITS VALUE.—Mr. T. Lange read the following paper:—"Select two five-acre to 10-acre paddocks near the homestead, fallow one paddock in winter, and harrow and cultivate it; have it well prepared so that it can be sown after the first rain after the middle of March. For sowing I prefer Cape barley at the rate of 1½bush. to 2bush. per acre, and not less than 1cwt. of super to the acre. When barley is about 6in. to 9in. long the cows can be let in for a few hours a day, but not in wet weather. Later on when growth is more rapid the cows can be left in longer. It is also very useful for mares, foals, and calves. When cut with a scythe it may also be given to the pigs. Prepare the other paddock with fallow the same way as that which was cropped last year. It is also useful to sow a paddock of stubble land for feed, say about 20 to 50 acres." (Secretary, E. Wurst.)

MORCHARD (Average annual rainfall, 13.59in.).

May 4th.—Attendance, 9.

TRYING TO MAKE FARMING PAY IN THIS DISTRICT AT THE PRESENT HIGH COST OF PRODUCTION AND LOW FARM COMMODITY PRICES.—Paper read by Mr. M. Brown.—"Making farming pay at the present prices is an impossibility. In this district wheat growing over the last 40 years has occupied most of our time with sheep and cows as sidelines. Wheat growing at present prices is a losing proposition, and prospects do not appear to be very bright at present. A man who has plant to work, say 400 acres, if he sows 300 acres will be able to cultivate a little better and devote the other 100 acres to livestock. This practice will give him a better opportunity to wait for rain to sow his crop, for the crop sown just after the first good rain is generally the best. Shallow cultivation and plenty of harrowing should be the rule. Any farmer purchasing a new tillage implement should try to buy the implement that will make a good job at the shallowest possible depth. Growing the wheat is not everything; there is the selling of it, and the man that sells over the tail of the wagon will come out as well as any on the average, and perhaps a little better. Power farming is too expensive at the present price of wheat. During the last three years the horse breeder has had a good harvest, and the good draught horse is still worth breeding for sale. Sheep at present is the brightest spot, but there is no guarantee that this coming wool season will yield such good prices. However, even with a 20 per cent. reduction in price wool is better than wheat at the present price, or even wheat with a 20 per cent. increase in price. Every farm should have a flock of ewes for breeding, and in this district ewes should lamb in August, when there is green feed for them. This will give a better percentage of lambs, and if marketed just after harvest there seems to be a fair local demand for them. This will pay just as well as trying to breed export lambs. At present it would appear that horse breeding

and sheep are the best propositions on the farm to-day. It is very hard to make much profit out of cows at present, and six cows are plenty for the average farmer. The milking Shorthorn is a good breed for this country, and the steers are saleable. The Jersey is a wonderful cream cow, but the steers are generally practically unsaleable unless there is a shortage of beef, and the reverse seems to be the position at present. Every farm has a few fowls which bring in a few shillings to help swell the income. In addition, every farmer should keep a couple of breeding sows of the Large White breed if possible, as there is generally a market for young pigs, and this type of pig seems to be most in demand by the bacon curers. A few pigs fattened for the Abattoirs market would also pay with wheat at such low prices. Sidelines appear to be the only chance of hanging on, and farmers must make a few shillings out of them wherever they can."

Mr. P. C. Schultz read a paper, "Trials and Temptations of the Farmer." (Secretary, E. Tillbrook.)

WARCOWIE (Average annual rainfall, 12.31in.).

May 29th.—Attendance, 14.

THE GROWTH OF PLANTS.—Paper read by Mr. F. Williams:—"Plants, whether they are grasses, herbs, shrubs, or trees, all derive their requirements from two sources—from the atmosphere and the earth. Contrary to popular belief, only a small portion of a plant's constituents is taken from the ground—about 95 per cent. is taken from the air in the form of carbon and water. That portion which is taken from the air returns to the air during the process of burning. That portion of the plant material which is taken from the ground is absorbed in the following manner:—It is assumed that the ground is moist. By this means the various constituents of the plant's nourishment can be in solution, as they—that is, the phosphoric acid, nitrogen, potash, &c.—are not available to the plant otherwise. This solution is "taken in" by the root hairs—the very smallest roots—by the process of osmosis, the process by which two solutions, a strong one and a weak one, change places with each other through a membrane. The weak solution always travels towards the stronger one much more rapidly than the strong moves towards the weak. The root hairs contain a strong solution—an acid solution. A small portion of this moves out of the root into the soil, and a large portion of 'soil solution' moves into the plant. This solution moves up the plant in much the same way as kerosene moves up a lamp wick. The 'drawing' or sucking is caused by transpiration from the leaves. The leaves of a plant serve a double purpose. The sun's rays draw water from them into the atmosphere, and cause the rise of moisture in the plant. They are also the stomach of the plant inasmuch as they prepare the carbon for assimilation by the process of photosynthesis. Photosynthesis is the process by which the chlorophyll (literally leaf-green) in the leaves combines water with the carbon dioxide in the air, and makes carbohydrates or starch for the plant. This starch is thus composed of much carbon from the air, and a portion of water and other foods from the ground. It is circulated all over the plant or tree to build up new tissues." (Secretary, A. Crossman.)

(PETERBOROUGH TO FARRELL'S FLAT.)

BEETALOO VALLEY (Average annual rainfall, 23.50in.).

April 23rd.—Attendance, 9.

PIG KEEPING.—Paper contributed by the Hon. Secretary (Mr. B. Giddings):—"One of the most essential factors in connection with this sideline is housing. The sties sometimes seen on farms are unfit for rearing or keeping pigs. Usually there is only earth for a floor, which becomes more or less a boghole in winter. A good sty can be built of stone or wood and iron. Not too many should be kept in one sty. That usually means fighting at the trough, and the pigs not getting an even share of the feed. Sties should be well ventilated; it is much easier to keep a pig warm in winter in a well-ventilated sty than cool in summer in a closed one. A good floor can be made of stones which are equally as good as concrete and much cheaper. The habits of the pig are naturally clean, making its bed each night if the bedding is

there for it, and using as a privy the corner of the sty farthest from its resting place. Pigs require plenty of exercise, especially when kept for breeding purposes, so that it is essential to have a yard conveniently adjoining the sty an area of half an acre would be ample, but the size would vary in accordance to the number of pigs kept. This can be erected by using sturdy posts 9ft. to 10ft. apart, and about 4ft. above ground with strong pig netting firmly wired to the inside of posts and four or five barbed wires inside of the netting 6in. apart to prevent the pigs rooting. A stand can be erected in the yard, and if peas were used for feeding can be stacked on it and the pigs fed from there, and no grain would be wasted. Otherwise straw can be stacked there and used for winter bedding; whichever is adopted would provide a cool, shady spot in summer for the pigs. Feeding depends mostly on what is available; not all owners grow special grain for pig feed. Peas make a very good ration if fed in the straw; they not only provide bedding, but make them exercise for the grain, which means that it is chewed more thoroughly than if fed loose and the animal allowed to eat it at will. Another important factor is that the land on which they are grown is enriched. Wheat or barley is considered the usual grain feed for pigs, but whatever grain is fed it should be well crushed or soaked so that it will be thoroughly digested. If milk is available so much the better, especially for young pigs. Any waste from the house, provided no soapy dishwater or bones are in it, can be fed. The trough should be cleaned out before putting in the feed. A forkful of greenfeed daily is very beneficial to sows, and if this is not procurable it will pay the breeder to plant some kind of green fodder. Mating can safely be done at 12 months—a little older all the better—but it does not pay younger. The best time to sell the young is at eight weeks old. If any are required for killing they can usually be bought at a good weight or as stores, and fattened to the desired condition cheaper than they can be reared to that size, unless the feeding is very cheap. The kind to breed usually depends on the breeder's fancy, but if Australia is to depend on her overseas markets—which she is trying to develop at the present time to dispose of her pig products—then the desired type must come from Large White boars crossed with Mid-York, Tamworth, or Berkshire sows. Pigs as a sideline at the present time can hardly be termed a payable proposition, but as the market fluctuates so rapidly it is not to be considered that it will always remain so."

BLYTH (Average annual rainfall, 16.80in.).

May 25th.—Attendance, 24.

CULTI-PACKING.—Mr. W. C. Johnston (District Agricultural Instructor), in the course of an address on this subject, said there were few advantages to be obtained by culti-packing and that the cost of the implement in comparison to the benefits derived did not warrant its purchase. Encouraging results were obtained at Veitch on sandy country, but if a culti-packer was needed in this district it was an indication of poor cultivation methods. Members, in discussing the subject, were of the opinion that culti-packing was not beneficial enough to warrant it being a general farm implement, but in special cases good results may be obtained, especially on sand.

THE IDEAL PIG FOR EXPORT.—Mr. R. H. Eime (Hon. Secretary) read the following paper:—"The pig required for export is also the pig required for local markets. Perhaps the word export has been added because local markets could not absorb the animals, and exports had to be made, but to compete with foreign countries in the British market the necessity of breeding the 'ideal' pig is brought more before our notice, and pig breeders must realise that the short, dumpy, fat pigs are of low value in Britain and are unprofitable for export. The confirmation of what is considered the 'ideal' pig has been brought under the notice of pig raisers by medium of the daily press and Bulletins published by the Department of Agriculture, but it will do no harm to again explain this type of long, lean, rangy animal. The head with jowl and neck should be light, as it consists largely of bone, and is of low value, and should not carry large rolls of fat at the jowl or over the neck. The shoulders and fore end must be light and free from wrinkles and coarseness. The back must be long and level, because the middle of the carcass fetches the highest price per pound. The fat on the back should not exceed 1½in. in thickness in baconers and in porkers considerably less. The sides should be level and moderately deep. The underline must be straight, as it denotes that the 'thin streaky' and 'flank' cuts are not unduly distended and thin. The belly should be thick in the flesh, as the value of the lower cuts is increased by thickness. The flank should be thick, handle firm, and be in line with the sides. The hams must be broad, wide, and deep to the hocks, as these characteristics denote plenty of flesh. There should be no depression at the root of the tail, as this denotes excessive fat. The legs should be set wide apart, and the pig should stand up well on the tips of its toes. The bone must be fine, as it indicates quality and does not detract from weight. The skin should be free from wrinkles and coarseness. The hair should be fine. The colour may be anything, but the trade prefers white pigs. The weights should range between 160lbs. to 225lbs. live weight

(120lbs. to 170lbs. dressed weight) for baconers, and 85lbs. to 120lbs. live weight (60lbs. to 90lbs. dressed weight) for porkers. The same conformation applies to both porkers and baconers; the only difference is in the weights. But the question is how to breed this pig? The trade prefers white pigs, because they have a better appearance than a dark coloured pig when dressed. The only way to get white pigs is to use a white boar, and I recommend a Large White. Suggestions are made to use almost any prolific, roomy sow—a half-bred Tamworth-Mid York cross or half-bred Tamworth-Berkshire cross. Perhaps the ideal pig may be secured in some of these crosses, but once past the first cross there is a danger of the progeny reverting to one of the other breeds. This will not happen in the first cross. Another thing which may happen in cross breeding is the appearance of black blotches on the skin. This can happen when using a Large White boar, but both parents must have some trace of blood of a Black, however far off. It is known that Large Whites may have a trace of 'Black' blood in them. When breeding a Large White this is not so prone to happen. I would breed pure Large Whites. At the 1933 Annual Congress Mr. Barlow had a side of a Large White barrow pig on view as the ideal pig. This pig was 4½ months old and dressed 124lbs. and at that time realised 65s. at the Abattoirs." Members, in discussing this paper, realised the importance of breeding the correct type of pig, irrespective of breed, but considered a Large White quite suitable. The importance of correct feeding was stressed, the addition of a small quantity of lime, and about 3 per cent. of meat meal to the grain ration was advised, especially if there was a shortage of skim milk. Some farmers are still inclined to breed a limited number of the old type pigs for their own consumption. Doubt was expressed as to whether local and export markets required the same type of pig, some holding the opinion that slightly fatter pigs were required for the local market.

WIRBARA (Average annual rainfall, 19.34in.).

April 28th.—Attendance, 14.

SELECTION AND TREATMENT OF SEED WHEAT.—Paper contributed by Mr. W. Stevens:—"It is a good plan to examine crops early in the year if it is intended to obtain a change of seed from any farmer in the district. In a district where there is a good deal of turnip this bad weed can be easily spread over a farm if a few bags of seed are purchased from a farm where the turnip is growing. In most years when there is a dry spell it brings the barley out in ear before the wheat, and it is then possible to see how much barley is in the crop. If wheat true to type is desired, it is necessary to wait until the wheat is out in head to detect heads of other varieties in the crop. When reaping wheat for seed allow the crop to become 'dead' ripe before keeping it for seed. There has not been very much smut in the district this last few years, but when it appears in a crop, the best plan is obtain fresh seed that is free from this disease. Grading is one of the most important jobs of preparing seed. Have a grader that will take out all the cracked and small grains. These latter will make good fowls' feed, or if put through the crusher can be fed to horses. When there is no smut in the seed dry pickle is best. Seed so treated germinates more quickly than that pickled with bluestone. Seed can be treated with any of the wet pickles before seeding, but the bags must not be stacked in the shed until the grain is dry. Formalin is a good pickle, but great care must be taken that it is not used too strong or it will kill the grain. In wet weather the seed must be sown within three days or kept for a week, otherwise it will take a long time to come up, and if the ground is wet, some of the seed is likely to rot. Seed sown in soil that is too wet will often rot before it will germinate." (Secretary, F. Borgas.)

YANDIAH.

April 13th.—Attendance, 25.

CROP ROTATION.—Paper contributed by Mr. C. Jettner:—"With the continued low price for wheat and the rise in wool values, together with the improved outlook in the export meat trade, farmers would probably be well advised to consider curtailing to a certain extent the wheat areas and increasing the number of livestock on the farm. The crop rotation practised in this district is principally wheat—fallow—wheat, which means that practically half the arable land is under fallow each year, leaving only half the land producing anything. By adopting a three-course rotation two-thirds of the land would be producing an income and only one-third lying idle in fallow, and thus the interest charges on working capital, land, and improvements, would be reduced by two-thirds of the land under production instead of half under the two-course rotation. What crop can profitably follow wheat in this district? Several points must be considered—the suitability of various crops for grazing purposes or for grain and their effect on the land for the following wheat crop. In the northern districts choice of crops to follow wheat is unfortunately limited as compared with the higher rainfall districts. Considered from every angle, oats are probably the most suitable crop to follow wheat. A fairly early variety, sown to come away with the first rains,

will provide good grazing much earlier than grass lands, and the stock returning to the soil the growing crop through the droppings will help prepare the land for the succeeding crop. Oats can also be sown for grain, and in fair average seasons the yield on stubble land is just as good as wheat on fallow. The grain is excellent stock feed, and if stored in an airtight bin, can be kept for years, making a splendid reserve in times of shortage of feed. Oats being resistant to many of the diseases which attack the wheat plant, tend to reduce these diseases, many of which are in the soil, and thus greatly increase the chances of growing a disease-free crop of wheat. Cape barley also does well on stubble land, and produces as good a yield as oats, but has the disadvantage of being susceptible to many wheat diseases, and thereby increases those diseases in the land. Wimmera Rye grass will also do well in this district, and 2 or 3 lbs. sown with the crop will produce quite good feed the following year at a small cost. By adopting a three-course rotation instead of wheat—fallow—wheat, cost of production per acre would be reduced, more livestock kept, thereby spreading the income over a larger number of lines, and any rise in values on these lines would be taken advantage of. The cost of producing a stubble crop is not nearly so great as a fallow crop, and by growing a variety of cereals and keeping more stock, the land would be kept in better condition than by growing the same cereal year after year." (Secretary, O. Borgas.)

POWER TRANSMISSION.

[Paper read by P. J. Curnow at the March meeting of the Wirrabara Agricultural Bureau.]

Where stationary machinery is to be installed a little forethought in the laying out of the plant, and later the study of various points in relation to belt drives and other forms of transmitting power, will help to smother working of the plant.

When putting in a power unit, such as an oil or petrol engine, for a specific purpose, as for chaffcutting, the possible future use to which such an engine may be put is worth considering. Later it may be desired to drive a wood-cutting saw, a grindstone, or similar outfit. If the engine is so placed that drives may be taken either right or left, or through overhead shaftings, then future additions to the driven plant may be made without difficulty.

To place an engine in a small shed attached to other buildings often makes it difficult to find space suited to other needs. An overhead shafting under these circumstances is the simplest way out of a difficulty.

All stationary machinery must be firmly based. A good heavy concrete block for a large engine is best, but a small engine may be bolted to a solid gum block sunk at least 3ft. in the ground.

When laying out any plant to be driven, care must be taken to have all pulleys in alignment. Too often in farm plants a little error in this regard means a belt that refuses to stay on the pulley. If correctly adjusted, belts rarely commit this offence.

BELTS AND PULLEYS.

The belt on any unit must be cut the exact length, allowing for a reasonable amount of slackness. Tight belts mean needless friction and worn bearings on the pulley side, in addition to loss of power from the driving unit.

To secure the greatest amount of energy from an engine and the driven machine, belts should drive from the underside of the pulley and not the top. A slack belt transmits all the power developed by the engine pulley, provided a good chemical substance is used to prevent slip. A belt so adjusted makes for easy power transmission. All belts must be cut square at the end, and fastenings adjusted to pull evenly. A belt badly or unevenly laced will often leave the pulley.

Bright pulleys mean slip or loss of power. Care should be taken in selecting a suitable belt dressing. A makeshift will often make a belt cling to the pulleys, but will seriously affect the leather or rubber belting. Castor oil will harden a leather belt and finally ruin it. All kinds of home-made dressings are sometimes used. A good belt with proper care will give many years of first class service and is worth a good standard dressing made expressly for the purpose.

Leather belting is suitable for all classes of power transmission, particularly for small machines and small engines. A good rubber fabric belt, too, give years of useful service.

When purchasing an engine it is wise to ascertain the normal working revolutions per minute, as it is then easy to find the size of pulley needed when putting in other plant.

A large engine pulley means a dangerous speed when power is transmitted to another unit with a small pulley. For instance, a small chaffcutter with a heavy knife wheel would collapse if an unsuitable pulley were used when driven from an engine running too quickly. At least a 20in. pulley on the cutter would be required. There is a safety limit in relation to all driven machinery, beyond which it is risky to go. A heavy

grindstone if over-driven will burst, and so will a heavy circular saw if run above a certain number of revolutions per minute. In these matters the size of the pulley on the driven unit governs the speed.

There are fixed rules used by engineering experts, which cover the whole subject of machinery installation, and any engineering firm supplying new machinery will make recommendations when approached.

Many types of bearings are now available. The newer ring oil form is most suitable for rapidly moving shafting, for lubrication is assured with little attention.

For shafting such as that used in overhead work, special plumber blocks, with correct methods for lubrication, are available. These are easily attached to walls or posts, and must be firmly attached, for vibration means wear and loss of power.

For special work roller bearings, although expensive, are much used in factory layout. Their use means ease of power transmission through loss by friction.

A few further points in connection with leather belting may be mentioned.

Experts agree that a belt driven from the grain or hair side will develop double the pulling power, compared with a similar belt driving from the flesh side.

So long as the original condition of belting is maintained, the best use is being got out of it; but lack of attention means deterioration.

A dirty, greasy belt may be cleaned by scraping with a wooden scraper, followed by a brushing with a stiff brush dipped in kerosene. Or another method is to wash in warm water, then grease and dry thoroughly. When belts are in constant use they should be attended to as soon as a too-dry appearance is noticed. A belt will generally slip more after a lubricant has been applied, but will soon grip as the dressing becomes absorbed. A too-constant application of a dressing will shorten a belt's life. Given reasonable attention a good belt will give years of useful service, especially where the other points mentioned are kept in mind.

LOWER-NORTH DISTRICT. (ADELAIDE TO FARRELL'S FLAT.)

BROWNLOW.

April 25th.—Attendance, 9.

BREEDING AND CARE OF HORSES.—Mr. G. Roocke, in the course of an address on this subject said mares from which it was intended to breed should be of a square build, short ribbed, flat-boned and, if possible, staunch and quiet. Care should also be taken in selecting a sire; bad points should not be overlooked, because the offspring were liable to have the same faults as the parents. It paid to breed good stock; a few of the reasons were:—A ready sale, attractive appearance, good and reliable workers. A mongrel would eat the same amount as a well bred horse, and yet the former would not keep condition like the latter. The Clydesdale was the most popular horse in this district. Care of horses should be practised in every way. Give plenty of good feed, and allow sufficient time for feeding during the busy times. Grooming was worth while. Horses should not be worked longer than from 4 to 5 hours in one run. If possible, accustom horses to watering before feeding. Great care should be taken with the harness; see that it fits well; also, care must be exercised with horses' shoulders; do not work them with sore shoulders, and do not ill-treat a horse. (A. Steinborner, Secretary.)

FRAYVILLE.

May 24th.—Attendance, 18.

Mr. C. B. Shearer gave a travel talk, "A Trip to America and Canada."

HAND FEEDING SHEEP.—The following question was taken from the question box, "Which is the best feed for hand feeding sheep?" Mr. W. Faehrmann recommended "oats straight from the harvester. Mr. V. Dohnt fed hay for a start until the sheep ate the heads off and then fed hay chaff and crushed oats. The result was that he

had 70 per cent. lambs. Mr. L. H. Watchel supported linseed meal and nuts for ewes. Before using this he had kept no lambs, but after feeding meal and nuts ewes had plenty of milk and looked after their lambs. The meal was fed in hay chaff at the rate of 20z. per sheep a day. He also stated that it was inexpensive. Mr. S. A. Bretag found that sheep did fairly well on "heads" left over from harvest.

April 9th.—Attendance, 23.

BLACKSMITH ON THE FARM.—Paper read by Mr. C. M. Roennfeldt:—"Under present conditions it is essential that expenses be kept at a minimum. In this direction the farmer oftentimes has to be his own saddler, bootmaker, carpenter, etc. The greatest time and money saver, however, is a blacksmith's shop on the farm. The initial cost of equipping the shop with the necessary tools, &c., may seem fairly large, but time will prove that money thus spent will be the best investment ever made on the farm. The shop should be fairly roomy—about 15ft. x 16ft. This would enable a fair-sized implement to be put under shelter in winter while it is being repaired. *Site of Shop.*—In choosing the site, care should be taken as regards the danger of fire in summer. An inexpensive shop can be erected as a lean-to against a stone or iron shed already on the farm. The north or north-east side can be left open, thus necessitating only 2 walls and a roof. The equipment should consist of 1½-cwt. anvil, £5; forge, £4 5s.; drilling machine, £3 15s.; stocks and dies, £2; vice and sundry tools, £2. This would consist of several hammers, tongs, hack saw, files, chisels and punches, wrenches, ruler, centre punch and drills for drilling machine, etc. Total £20. Interest on this sum at 5 per cent. equals £1 per annum. These prices are for new tools, but at sales it may be possible to buy the above-mentioned in good order at less than half the price. Punches and chisels can be made out of old rasps or files or pieces of steel. For the forge I favor coke. It makes a cleaner fire, but goes out very easily. A few pieces of charcoal will help to keep the fire going. The amateur blacksmith's motto should be 'Be exact.' All measurements should be taken to an eighth of an inch, and all places for drilling should be marked with a centre punch. When iron is to be bent, mark all corners with a centre punch. When taking anything to pieces care should be taken not to mix the nuts. Each nut fits best on the bolt from which it was removed. Keep all tools in their proper place and put them back after being used. This will save much time and worry in trying to remember where they were last used. The best time to repair machinery is after using, when worn parts are fresh in mind. Be careful to hold the tongs correctly; if not, the hot iron will be frequently dropped instead of hammered. When bending iron, see that the tongs are holding the iron from above, and the cold end of the iron is resting against the bottom of the tongs. Iron must be worked very hot, otherwise the ends are likely to split. If they do, put back in the fire. Heat to welding point, weld the split and continue. When making a fitting or any article that requires a lot of hammering and twisting, do not use iron; get a new piece of mild steel. In most cases the iron cracks or breaks when nearly finished without any apparent reason. When drawing round iron to a point, draw out as if it were a harrow tine. When drawn out sufficiently, break the four corners and it is practically round again. *Welding.*—When welding, most amateurs experience some difficulty. However, with a little care and patience some success should be achieved. Before attempting to weld see that the fire is absolutely clean; all clinker (melted coke or coal) round the blast hole should be removed. This is important. Old iron is easier to weld than mild steel. When welding two bars, first stanch back each end to be welded, then draw the ends to a slanting point or lip. When putting into the fire, see that the lip of both pieces is turned upwards. If the lip is placed downwards the chances are that as the heat comes from the bottom, the thin lip will burn off before the thicker part is hot enough. Make a strong blast up and see that both pieces are heated evenly. When the part to be welded is white, and small white sparks are seen coming out of the fire, the iron is hot enough to weld. The bar which is to be at the bottom must be turned whilst being put on the anvil. The other piece being placed into position and ready for hammering, see that the lips are welded down first; they are the thinnest part of the iron, consequently rapidly cool down. Care should be taken not to hit thin bars too hard because the iron is very soft when at a welding heat. The thinner the iron, the quicker it gets cold, therefore have the anvil close to the forge. Do not use any coal or coke in which any brass or galvanised piping has been heated for welding purposes. When working any iron or mild steel, make it fairly hot; it is easier to work and requires less man-power. The difference between steel and iron can be told by the ring when dropped on the anvil. Iron has a dull ring or sound, whereas steel has a clear ring. *Tempering.*—When tempering picks or chisels, place in the fire, and heat to a bright cherry red. When hot enough, place about 1in. of the point in cold water; take out water and different colours will be noticed working down from the hot end to the point. This actually is the heat working back to the point. When the colours are almost at the point, cool off suddenly. The chisel should

only be hard at the point, otherwise it will snap. If the chisel is too soft, make it a shade hotter before tempering; if too hard, not quite so hot. A little practice and the amateur blacksmith will become efficient. Nuts that refuse to come off old bolts, if placed in the fire until red hot and then plunged into water can be practically unscrewed with the fingers. Iron gates out of old buggy tyres, and iron swings out of old scrap iron, can be made with little expense. It is surprising the hundred and one things that old scrap iron can be transformed into by the handy man. It provides pleasant occupation to the man on the land on rainy days." (Secretary, A. Schubert.)

GREENOCK (Average annual rainfall, 21.57in.).

April 30th.—Attendance, 25.

PIG KILLING AND SAUSAGE MAKING.—Paper read by Mr. Keller:—"Strict cleanliness must be observed in all work connected with small goods. First the weather should be studied carefully before killing; settled, cool weather is essential. Starve the animal for 12 hours before using the knife on it, then bleed the pig well and give the carcass a quick scald. The pig should be killed in the sty by shooting it with a .303 rifle carrying cartridges loaded to half strength. When sticking a pig, turn it on the right side, then insert knife 2in. in front of the breast bone. When the knife is in, press the handle down a little to raise the edge of the blade to cut the jugular vein. For scalding I prefer a roomy trough, 6ft. x 2ft. x 1ft. will answer the purpose up to a pig dressing 400lbs. The carcass should be ready for scalding a few minutes after killing. Keep on turning the pig until the hair and skin come off easily, and then add a little cold water to prevent it from over-scalding. When the carcass is scraped clean, hang it up at a convenient height for disembowelling. First remove the head, then clean it thoroughly, and cut it up to put in the copper to boil. Put the meat in straight away to boil, so that it will be cooked when the carcass is dressed. To do this, make a cut from between the hind legs and continue right down, first cutting off the dummies. Care should be taken not to cut too deep and puncture the intestines. To avoid this, place one hand in front of the intestines and guide the knife between the fingers. After cutting right down, chop the breast bone and the bone between the hams, which will make the dressing more convenient. Then start at the top between the hind legs and remove all intestines and stomach, but just before doing this securely tie the end bowel. Next cut out the lining between the stomach and lungs and remove the heart, lungs, and windpipe. This should leave the carcass clean and unsoiled. The carcass should be left hanging in an airy place

COMPARE YOUR COSTS!

CATERPILLAR

DIESEL

"Thirty - Five" TRACTOR

In the Clare District cultivated 800 acres in 175 hours
on 275 gallons of fuel costing 6 1-8d. per gallon, i.e.,

A FRACTION OVER 2d. PER ACRE.

A similar model is now on view at

THE S.A. TRACTOR CO.,
231 Flinders Street, Adelaide.

If you cannot call—write for particulars

until next morning to set. Early in the morning cut down the carcass on both sides of the back bone. First cut out the hams, then the shoulders, the sides are then trimmed by cutting off surplus fat on pieces of meat. Then the ribs are taken off, cutting as close to the bone as possible. Keep it smooth in order not to remove too much of the lean flesh of the bacon. After trimming the hams and bacon it is ready for curing. All trimmings can be saved and put in the metwurst. *Curing.*—The pieces of pork should first be well rubbed with a mixture of salt and saltpetre, then place flesh down in a pickling cask and allow them to drain for 3 or 4 days before the brine is put over. This is to remove all the blood from the meat. *Brine.*—Salt, 5lbs., saltpetre 1lb., and 2½galls of water. Then smoke until rich brown.

White Pudding.—Two cheeks, liver, flanks, 2 loaves of bread. Pepper and salt to taste; 1 large onion, a handful majoram. Boil liver 20 minutes, and cut off all the rind of the meat used in the white pudding.

Black Pudding.—Take all the parts of the head that are left, also lungs, heart, and kidneys, all the rind that is cut off the meat used in the white pudding, 3lbs. of boiled rice, and salt, pepper, and allspice to taste, and 2 handfuls of majoram and as much blood as desired.

Metwurst.—To every 8lbs. of meat add 4ozs. salt and ½oz. of saltpetre, about 1 handful of pepper to 10lbs. of meat, 1 wineglass full of brandy, and 1 dessertspoon of sugar. (Secretary, A. Schubert.)

LIGHT'S PASS.

March 26th.—Attendance, 15.

Junior members Ron Hahn and Fred Boehm read papers on "Packing Apples for Export" and "The Codlin Moth." Mr. B. Boehm gave a report of the visit made by Branch members to Mr. N. Wicks' nursery at Highbury. Mr. F. Gunter addressed the meeting on "Manures." Mr. W. Ahrens tabled an excellent sample of locally grown Smyrna figs.

FROST CONTROL.—At the April meeting, which was attended by 25 members and visitors, Mr. L. Plush read the following paper:—"Crops can be definitely saved by artificial means, proved by the test carried out in Mr. Bert Boehm's orchard by Mr. J. B. Harris (Orchard Instructor on behalf of the Department) last year. It does pay to protect apricots, peaches, currants, and vines. There are a number of ways in which frosts have, and are being fought; among the best known are smudging, flooding, covering, circulating the air, and heating. Smudging, by making a smoke screen, has proved unreliable here. It has given definite results one night and may be a failure the next should a black frost occur. Flooding is practised successfully in different parts of the world where ample water is available and the land is suitable for it. Covering.—I only know of one case of this method being done commercially in Australia, at Red Cliffs, Victoria, where an orchardist covers about 15 acres of sultanas with strips of bran bags, cut about 12in. wide, stitched together, wound on to rollers and pulled over the trellis by means of a small windlass. The bagging is kept several inches above the top wire. These are kept on during the danger period. It has worked quite successfully during two white frosts. In Germany vines are taken off the trellis, laid on the ground, and covered with sand, thus delaying the bud burst until the frost menace is over. Circulating the air has proved too expensive, but has been done successfully by the use of explosives, and by the use of fans pumping the warmer upper air downward. Heating with oil will be the universal means of attacking frosts in this State in the near future. It is still in its experimental stage here at present, but will spread rapidly as soon as growers find that it is not so expensive as was at first thought. Oil heating will ultimately be the cheapest and surest means of frost fighting. An acre of apricot trees in full bearing should yield an average crop of 4 tons of fresh fruit annually, valued at, say, £8 per ton equals £32 of fruit for the acre. The cost of oil for that acre (one frost) at 6d. a gallon would be £1 10s., plus interest on capital outlay and depreciation (10 per cent.) on plant would be roughly another £1, making a total of £2 10s., thus showing a profit of £29 10s. over a similar acre that had not been heated. The whole plant sufficient to save an acre would not be much more than £8, plus oil, for at least three burnings. These figures are based on 60 heaters to the acre. Another important point to remember is that one must reckon the gross profit and not the net profit. It is necessary to prune, spray, cultivate, &c., whether a crop is received or not. The equipment needed for a local grower would be about 60 to 75 lard pail heaters (5 quarts) to the acre, costing about 1s. 9d. each for 150 lots; several tested thermometers; an electric alarm thermometer—there will be two of these in the district this year—and lighting torches costing about 15s. each. These prices may be improved on by buying in larger quantities. A storage tank and a tank wagon for distributing the oil would be very useful to larger growers, whereas a few old oil drums would suffice for the small grower or for the man who is starting in a small way. The heaters are usually placed in the centre of each square formed by four trees, with a double row on the windward side of the orchard. When filled the lids are placed on them to

keep out the rain. The temperature as a rule does not fall much below freezing, and equipment to raise the temperature 4° or 5° is all that is necessary. Whenever heaters are started the grower should be able to keep them burning until after sunrise. The lard-pail heater will burn for about 3½ hours. When the temperature falls below 32° only about half are lit, and the temperature is noted. The temperature should never be allowed to rise much above 32°, but as it falls below that mark light more heaters. The reason for not raising the temperature above the 32° mark is for economy. One or two extra degrees of warmth burns up a lot of extra fuel that may be required later on in the night. Spare lighting fuel for the torches should always be kept handy. This is a mixture of equal parts of petrol and kerosene. A few drums of spare oil should also be distributed in the orchard in case of a long frost, when it may be necessary to replenish the heaters during the night or early morning. The Americans have two or three heaters placed together and only one lit, in case of long frosts, to save replenishing during the night. Replenishing can be done with a watering can with the rose off without having to extinguish the heater. Wood fires were tried out last year in braziers and open fires, both being quite satisfactory and cheap so far as fuel is concerned, but the amount of work that has to be put into it and the time it takes to light up as compared with oil rather puts wood out of the question against oil, especially if any large area has to be heated. I have mentioned black and white frosts. The white on the ground or on any object is frozen dew. A black frost freezes before the dew starts to fall. That is, the atmosphere is very dry, and dew point may be as low as 25°, and no white may appear, but every water trough would be frozen. These black or dry frosts are the worst, and frequently occur with a light breeze or drift. In America they call these black frosts "freezes." I am inclined to believe that frosts are becoming more frequent, and the only reason I can offer is the destruction of so much timber, especially in the hills and higher ground. The trees hold the warmth longer than bare ground, and help to stop radiation to a certain extent, whereas now the ground in the high lands cools off more rapidly and drifts down to the low lands, thus causing more frequent and worse frosts than hitherto." (Secretary, C. Verrall.)

SUTHERLANDS (Average annual rainfall, 10.88in.).

May 3rd.—Attendance, 22.

POULTRY AS A SIDELINE ON THE FARM.—Paper read by Mr. E. Twartz:—"At present farmers in this district are in financial difficulties through bad seasons and low prices. It is therefore necessary to turn to sidelines as a means of balancing the budget. The rearing and keeping of poultry is not only a profitable sideline, but an avenue for the disposing of wheat. *Sheds*.—It is advisable to have the sheds fairly close to the house. This saves time and fowls can be kept under observation. It is essential that the sheds should face the north, to shelter the birds from cold east winds. I recommend the semi-intensive system, for by this method the fowls are kept away from the implements and vehicles. *Roosts* should be at least 3ft. high, and care taken to see that they are strong and firm enough to support the birds, especially the heavy breeds. Concrete water troughs are better in the hot weather—the water always keeps cooler. *Making a Start*.—There are several well-recognised methods of making a start. (1) By purchasing day-old chicks and rearing them to maturity. This has its drawbacks, because one does not know whether the chick was hatched from a 2oz. egg or not. (2) By purchasing a pen of breeding hens and hatching their eggs either with an incubator or under broody hens. (3) By purchasing fertile eggs and hatching them. Chickens hatched artificially are, in some ways, superior to those brought out under a hen. Broody hens almost invariably become more or less infested with lice, owing to their prolonged inactivity. Some of the pests transfer their attention to the chickens as soon as they are hatched, with the result that the youngsters start life with a severe handicap. A hen will hatch more chicks in comparison to the number of eggs set. This may be the case occasionally, but far often the hen produces far less when losses from breakages and other accidental causes are taken into account. August and September are the best months for hatching and rearing chickens; the pullets start laying in autumn when there is a shortage of eggs due to the moulting season. It is not advisable to hatch in either February or March. Chickens which are not hatched in the right time are not the best. *Mash*.—For best results the fowls should be fed on a mash—either wet or dry. The wet mash gives a slightly better return than the dry, but it means more work. It is necessary to mix the wet mash and give it to them every morning, whereas with the dry it is only necessary to fill the hoppers when they are empty. This is the more practical, because more fowls can be kept with the minimum of labour. *Greenfeed*.—It is necessary that the fowls be given a plentiful supply of greenfeed. The best plan is to grow a plot of lucerne, which, when watered, grows throughout the summer. It can also be chaffed and fed to fowls when no other greenfeed is available. The following mash is recommended:—Bran 20lbs., pollard 30lbs., meat meal 5lbs. (Secretary, E. Schiller.)

GENERAL MANAGEMENT OF FARM HORSES.

SUTHERLANDS (Average annual rainfall, 10.88in.).

April 5th.—Attendance, 17.

[Paper read by Mr. E. Schaller at the April meeting of the Sutherlands Branch.]

The horse has been described as "man's noblest friend"; he richly merits the designation. He is the chief source of power, and often the only one, on the farm. His peculiarities should be carefully studied, because a personal acquaintance with the peculiarity of temper and constitution of the individual of the team is absolutely necessary in order to become a good horse master, and his management should be on lines calculated to ensure his maintenance in a high state of efficiency.

For general farm work the nuggetty, medium sized, active animal with lightly haired legs has no superior. A big, heavy horse can never keep pace with a fast-moving team of free workers, and it is cruel to try and make him do so. Too much hair on the legs is a great disadvantage where horses have to work on sticky cultivated land. The mud sticks to the hair and forms big lumps, which soon become dry and hard.

Work the fast horses on the rein where you have more control over them; the team will then also go square up to the corners, and if both reins are kept taut the horses turn the corners without treading on each other's hoofs. In the team, care must be taken that all chains are equal and each horse pulls its fair share.

FEEDING.

This is the most important item of horse management, and the horsemaster must use his own discretion to a great extent. The mangers should not be filled and then wait until empty before another refill. The horse should receive at each feed just sufficient fodder as he will reasonably clean up. Under natural conditions the horse is a bulky feeder, and under working conditions bulk is essential to his feed, and even where concentrated feeding is resorted to, the admixture of chaff prevents over hasty feeding, and promotes digestion.

However, the stomach of a horse is small, and it is evident that severe labour cannot be safely carried out on a full stomach, therefore feeds during hard work should be small and concentrated. Breakfast may be bulky, because some time elapses before work is started, and digestion has proceeded to a stage that will prevent an over-gorged stomach. Dinner should be a small and concentrated feed, because time for digestion is short, and weariness of the flesh will interfere with it. The bulk of the feed can be given in the evening, because there is plenty of time for it, and no work to follow.

Oats rank as one of the best grains for horses. They combine all the elements necessary for nutrition in such proportions that the animal is able to consume a large amount without upsetting the digestion, and to extract the greatest possible amount of nourishment from it. Oats have been found to be the finest feed for horses of speed and those in very hard work. Horses are very fond of this feed, and will eat it in preference to all other grain. It probably comes nearer the requirements of a concentrate for horses than any other grain. The kernel is encased in a hull, which adds to its value as a horse feed. Oats may be fed whole or crushed.

WATER.

"Water first, feed afterwards" should be the general rule, because a horse's stomach is small, and water passes directly through the small bowel into the larger one, carrying masses of undigested matter with it. But it is not always possible or convenient to water before feeding, and the horse very often has a mind of his own, therefore, if one to 1½ hours elapse between feeding and drinking, stomach digestion is well advanced. Also arises the question, "Should the horse drink when hot?" It will not hurt him at all if he is used to it, and on the farm the walk in from the paddock will in most cases have cooled him down sufficiently. Should any particular horse be inclined to drink too heavily or be griped in consequence, his trouble will cease if the bit is left in his mouth when drinking, as it prevents him from taking too much. The over-tired horse may gripe with very little, therefore special care should be taken. For over tired, thirsty horses, a handful of oatmeal or pollard stirred in their drink is very beneficial; the main drink can then be postponed until later.

GROOMING AND COLLARS.

The working horse, if in hard condition, cleans himself to a great extent by sweating, and a roll before returning to the stable gets rid of most of the dirt. But in the morning he should be thoroughly groomed. The secret of the art of grooming as an aid to condition is to carry it out with speed and a will.

Care of Shoulders and Fitting Collars.—After a long spell and when work again is resumed the horse's shoulders should be washed with cold water immediately the collar is removed; this will harden the shoulders and prevent sores. For young horses, as an aid to hardening or toughening the skin of the shoulders, these parts can be

swabbed daily with a strong solution of salt or an extract made by the boiling of wattle bark, and if brought to work gradually there should be no trouble with sore shoulders. The shoulders where the collar sits must be kept clean and free from accumulations of dried sweat, grime, &c., that are likely to set up the chafing of the skin. Likewise, the linings and stuffing of the collar should by regular attention be kept clean and soft instead of being allowed to become caked and hard with sweat, grime, &c.

Every horse requires its own collar, which should be properly and carefully fitted to him, and any necessary adjustments made from time to time as the horse gains or loses flesh. Remember that a collar that fits a horse when in good flesh will not fit him when he gets poor, and *vice versa*. The collar should fit sufficiently close to enable it to lie quite flat, and bear evenly on both shoulders. If pressed to one side it should allow the flat of one finger to pass all the way down between it and the shoulder. The collar must be short enough in length to prevent undue rising, but not so short that it will press on the gullet or windpipe. The test is that the hand and wrist must be able to pass easily between the throat of collar and the neck of the horse. New collars are a frequent source of sore shoulders. Be sure they fit, and see that the horse is given easy work until the collar is moulded to the shape of the shoulders.

SHOEING HORSES.

On many farms draught horses are not provided with shoes except, perhaps, in the wheat-carting season, when it is necessary for the teams to travel on the metal roads. When shoeing is properly performed and the farrier has knowledge of the structure of the foot and the correct method of treating it, the results are quite satisfactory. In too many instances, however, there is both a lack of knowledge and a want of care, with the consequence that serious trouble often occurs.

The frog is a most important part of the foot, and has many useful properties. It prevents the heel from becoming contracted. It supports the leg in a valuable manner, whether the animal is at rest or in motion. It prevents undue concussion, and with the heels and bars prevents slipping. Therefore, the frog should never be touched unless, of course, it is necessary to remove a nail or dirt that may have accumulated in the cleft or amongst the flakes. The following rules should be adhered to as nearly as possible in the shoeing process:—(1) Bring the wall down to what it would be if natural friction had existed. (2) Fit the shoe to the outline of the foot; rasping the outside of the wall makes it weak and brittle. (3) Never run the rasp over the outside of the wall, as it has a waterproof coat to keep in necessary, and out, unwanted moisture. (4) The bars should not be cut away, as they are weight carriers, and the shoe should rest on them. (5) The shoe should have a true and level bearing on the walls and bars, and be as simple as possible, only sufficient nails to keep it firm, and only as high as is necessary to hold.

IN THE STABLE.

Horses as a general rule are more comfortable overnight in small yards than they are tied up. If in a mob together, the bullies will keep them on the move, and deprive them of rest and feed, but if the stable is divided into yards to hold several horses they will settle down and are easily handled. Provide proper stabling; see that there is shade in summer, and protection from cold winds in winter.

The stable should be kept as clean as possible, and a bedding of straw put down for the night if the floor of the stable is wet. Should it be possible to keep the floor dry, the need for bedding should not be so great.

THE IN FOAL MARE.

The mare's place in the team should be that which enables her to work without jerks, and avoid squeezing by other members of the team. The swing should keep the chains broad enough to prevent the chains from pressing on the abdomen; this will greatly minimize the risk of accidents whilst working.

CARE OF THE FOAL.

The first fortnight after the birth of the foal is the most critical period in its life. At this tender age, when least capable of offering resistance, he is specially liable to accident or disease. If the bowels are normally active the foal will empty himself in the course of the first two hours after birth. Where this does not take place, an enema of milk-warm water, with a little soap and glycerine dissolved in it, should be given, and if necessary repeated in half an hour. If the mother has to be put to work, care must be taken that the foal does not drink the overheated milk. This can be overcome to a certain extent by slightly milking the mare just as she comes in from work, and so drawing off the heated milk. If this cannot be done, the foal should be kept from the mare until she has cooled down sufficiently. Heated milk will upset the youngster's digestion, and very often result in the death of the foal.

The foal should be weaned at five to six months old, and then reared in such a manner as will avoid any possible check. If stunted during the first year of the foal's growth, it will never fully recover.

TREATMENT OF WOUNDS.

Wounds open to the air or only covered by a light protection heal much more rapidly than those wrapped in filthy bandages, which are supposed to assist because they have been dipped in some irritating antiseptic. Stitching up a wound is the finest way of keeping harmful germs in, and introducing them if not already there, that can be imagined.

In the dressing of ordinary wounds the following will generally suffice:—First: Provide good drainage. Second: Keep up a good blood supply by keeping the horse in a good, healthy condition. Third: Let the air play freely on the wound surface. Fourth: Clean the wound with some weak disinfectant. Fifth: Clear away dead tissue if present. Flies may be kept away by pine tar, eucalyptus, kerosene; if maggots get into the wound, petrol will bring them out, and turpentine will help the tissues to heal; but once maggots get in a wound they must be searched for every day, as they prefer working in rather than out.

March 12th.—Attendance, 12.

LESSONS FROM 1933.—Messrs. A. L. Molineux and D. G. Kelly gave papers dealing with this subject. The two main points learnt during the year were:—(1) Avoid poor fallow by ploughing early and working well in the spring. (2) Learn what wheats to sow and when to sow them. Mr. Molineux stressed the folly of sowing shell grit on land in this district. Mr. D. L. Clarke pointed out that while poor fallow would sometimes grow good crops, the best crops were usually grown on the best fallow. Members discussed the question of the quantity of superphosphate to sow, and condemned the practice of cutting down the quantity per acre. (Secretary, N. Clarke.)

UPPER WAKEFIELD.

April 26th.—Attendance, 22.

Mr. W. C. Johnston (Agricultural Instructor) addressed the meeting on "Noxious Weeds and their Eradication." The speaker emphasized the fact that to effectively control noxious weeds it was necessary to pull them up; if hoed they would most likely shoot again. The most serious noxious weeds mentioned were wild garlic, soursob, wild onion, blanket weed, mustard, Jamestown turnip, artichoke, star and saffron thistles, and stinkwort. (Secretary, C. Neumann.)

COWS ON THE FARM.—Mr. S. Heinrich read the following paper:—“It is almost impossible to do without at least one cow on a farm, while the keeping of two will ensure a regular supply of milk and its products right through the year. Many will remember the time when a small herd of cows proved a better proposition than pigs, sheep, and wheat, but since the price of butter has fallen, one has to look for another source of income if farm sidelines are to be made a paying proposition. It is a mistake to say that cows do not pay, even if it be only one or two; their real worth is not appreciated until they have been disposed of. To obtain an equal proportion of cream all the year, three cows at least are necessary, and care must be taken to see that all the cows do not go dry at once, and that the majority come into full profit when the price of butter is likely to be at its best—from March or April onwards until about October. Since February 2nd to May 29th my herd of five cows has consumed 14 bags of crushed barley at 6s. a bag, and 10 bags of bran at 7s. 6d. a bag, a total cost of £7 19s., and cream and butter returns amounted to approximately £12, leaving about £4 profit for three months’ work, besides supplying the household with milk, butter, &c. Taking the season into consideration, the money put into cereals for the cows will be well repaid as soon as the feed makes better growth; the cows go right ahead instead of waiting to pick up condition. Most farmers keep cows only because they want the milk and butter and leave the women folk to look after the animals. The farmer thinks they are a nuisance and that either sheep, pigs, or poultry pay better. Nothing goes well if you have no interest in it. Why not select a pedigreed animal of the breed that is fancied. Take the Shorthorn; it is a fairly good producer, and there is a fair market for any bull calves that are not kept for further use. I prefer the Jersey; a nicer and quieter cow no one could wish for. If treated kindly they can be handled better than any other breed, and are not troublesome to fences. It is a wise policy to breed nothing else than pure bred. A crossbred cow is often a good producer, but if one continue such breeding the result will be mongrels. For the 12 months ended March 20th, 1934, my wife milked three cows for 2 months, and one cow for about six months—equal to three cows for 13 months. During that time she made 640lbs. of butter at a net return of £23 7s. 7d., and sent away 90galls. of cream, showing a return of £11 1s. 1d., a total of £34 8s. 8d. The expenses were:—1 bag of linseed meal, 17s. 6d., 5 bags crushed barley £1 10s., 11 bags of bran £4 8s., and 6 bags pollard £2 7s.—a total of £9 2s. 6d. Deducted from £34 8s. 8d. leaves a net profit of £25 6s. 2d.—approximately 10s. a week. These cows are not claimed to be record butterfat producers. Jersey cows are quiet, but the bull is not to be trusted. Keep a bull for breeding purposes, for a good bull is half the herd. All bulls should be locked in a small yard or paddock with plenty to eat or drink, and even the quietest of them should never be trusted.” (Secretary, R. Hasting.)

SEEDING.—The Hon. Secretary, Mr. K. Trigg, read the following paper:—“In making preparation for seeding it is necessary to start at harvest time—the practical farmer will at this time select seed for the coming season and see that he obtains seed to suit his particular type of land. When the seed is chosen it is in the farmer’s own interest to see that it is properly cleaned in order that it will run through the drill or combine in the desired even manner. I favour dry pickling—not only because tests have proved wheat to germinate better under this treatment, but because it can be cleaned and pickled in one process, thus saving another handling just prior to seeding. I have used dry pickled grain in the same drill for four successive years, and the rollers are running as free as ever. There is one thing that does need cleaning regularly—the super stars. Unless these are running smoothly there is much undue strain on the main driving parts, and on one particular make of drill will

repeatedly break the main casting unless the stars are running freely. Each farmer must use his own discretion about the time to sow each different variety of wheat as a lot depends on this. Just after harvest and before seeding is recognised as the time for the horses' holiday. After running on the stubble and then being put to the preparation of the soil for seeding, sores are likely to show themselves, and it behoves every farmer to pay strict attention to this, his truest dumb friend. Go over chains and swings for they can be the means of causing much delay. When a combine is used on heavy land light harrows should be used to level it off, thus making it much easier on implements that have to cross the working. Keep the drill well covered when it is wet to prevent the super getting wet."

In the discussion that followed it was the general opinion that wheat that had been pickled the previous year need not be pickled again for seed. Messrs. Palm Bros. made it a practice to only pickle where they were going to reap for seed, thus saving much time in pickling which was deemed unnecessary every year. Heating the super stars was a method that was suggested instead of scraping each star.

April 7th.—Attendance, 19.

TRANSPORT.—In a paper on this subject Mr. J. S. Atkinson outlined the history of transport methods in the district before the erection of the railways and up to the present time. There was always the need of quick transport for primary produce, and transport development must take place just as advances have been made with cultivation methods. The railways catered for heavy traffic, and at present the motor train arrived on Tuesday nights and a goods train on Wednesday afternoons. A few years ago it was pointed out that the district was not advancing in the disposal of primary produce such as cream, butter, and eggs, and the branch secured a permit for freight service. This service had shifted a considerable amount of produce on behalf of farmers and the district as a whole. In the first year the value was £1,800, second year £2,600, and last year £4,000. The value of skins alone during last year was £687. The service commenced with a ton truck, then a 30-cwt., while last year it became necessary to purchase a 2-ton truck. For the future the carriage of livestock would have to be considered. The truck now in use has made 82 trips to Adelaide within 12 months, and the service was the largest in the State. (Secretary, F. Illman.)

June 2nd.—Attendance, 38.

The monthly meeting was held at Mr. J. E. Beinke's residence. The annual report of the activities of the Branch was presented by the Hon. Secretary, Mr. F. R. Illman. An excellent paper, "The Sheep Blowfly," was read by Mr. F. K. Parsons.

WARRAMBOO.

May 11th.—Attendance, 10.

RABBIT DESTRUCTION.—Paper read by Mr. A. Wagner:—"Each landholder should destroy rabbits wherever possible. The quickest method is by poisoning after the first rain with a poison cart, distributing phosphorised pollard and bran baits to which a few drops of aniseed oil have been added. After poisoning, all burrows should be worked in on the cleared land and in the scrub; then all rubbish and trees on and around the burrows should be cut down and thrown on the burrows and burned on a damp day. Dry weather is the best time for any fumigator, as the fumes have much more effect than when the air is damp. Bi-sulphide of carbon is very good for killing rabbits in burrows. The best way to use this is by pumping it into the warrens, or putting a little on a small piece of bag and then pushing it down each hole as far as possible with a stick. Close all holes except one in the centre of the burrow. In this one stand back and drop a match into it, and it will explode through the whole burrow, and will kill most of the rabbits in the burrows. The exhaust gas of an engine is very deadly, and I have had very good results with this method. It is slow but effective." Mr. Crawford found S.A.P. the best for baits, and recommended adding a few drops of aniseed to the pollard. Mr. J. Sampson recommended ploughing in the burrows in summer. One day in summer was worth a week in winter for destroying warrens. (Secretary, F. Chilman.)

May 8th.—Attendance, 12.

FARM ECONOMY.—The following paper was contributed by Mr. C. Spriggs:—"Although the cost of production has been brought down as low as possible in most instances, there are many small avenues where economy can be more rigidly enforced on the farm, and with a little foresight the farmer may save himself many expenses. A very profitable investment on the farm is a blacksmith's shop so that minor repairs can be made to implements, thus saving blacksmith's bills and valuable time. Take

good care of harness, and give it a greasing at least twice a year to protect and preserve it. A good grease for harness is about 50-50 clean unsalted mutton fat and sump oil strained from the crankcase of a car. It can be used in the poultry yard, and if painted on perches will kill lice and tick. Another very important saving is the super bags, which should be washed as soon as emptied. A good place is an old water-hole or disused dam, and left there to soak at least three days. They should then be hung out to dry, and will be strong enough to hold seed wheat the following year. Grow a few vegetables on the farm. Sheds for implements should always be provided; if iron is too expensive a cheap shed can be made of straw. If the implement is left in the weather the woodwork soon deteriorates. A good coat of paint or oil on same is a sound investment. See that reasonable stacks of hay are conserved in years of plenty. At least two years' hay should always be on hand. Another way to protect profits is to cart out manure on to hard red patches of soil—it tends to loosen them. Hoop iron should always be saved; it often becomes useful around the farm. Bagging around bales should be sown together for a tarpaulin to cover benches of the haystacks against fowls. They can also be used as sides for a cocky chaff wagon, as a covering for plants on the hot days, or as a windbreak. Old iron, kerosene tins, boxes, and binder twine should be saved when chaffcutting; it can be used in many different ways, and so help to bring down expenses." Mr. A. Spriggs, in commenting on the paper had found mutton fat and sump oil equal to neatsfoot oil as a harness preservative. Mr. H. Kobelt thought stable manure could be spread on sandy soil to better advantage. Mr. W. Brown pointed out that more care should be taken with sheepskins; they soon deteriorated if left in the weather. A good preparation for sheep skins was Cooper's powder sheep dip dusted finely over the skin before it was dry. Mr. F. Jericho gave a demonstration on setting a rabbit trap that he had made and patented. Members thought it would prove a success. The patent did away with paper, and gave the rabbit more plate space than the ordinary tin patent rabbit trap. (Secretary, E. Spriggs, Cleve.)

EASTERN DISTRICT.

ALAWOONA (Average annual rainfall, 10.29in.).

April 10th.

FUNGUS DISEASES OF THE WHEAT CROP.—In the course of an address on this subject, Mr. R. L. Griffiths (District Agricultural Instructor) said take-all had been very prevalent throughout the Murray Mallee during the past year, no doubt due to seasonal conditions which were suitable for the spread of the disease. Although rainfall was above average, there had been no heavy rains throughout the year to consolidate the soil, so that conditions were suitable for the spread of the disease. Some farmers thought that every district had to go through a period when take-all would be bad. This was not so, and by employing the proper method of cultivation it could to a large extent be controlled. Mr. W. Paull said in the Lameroo district when take-all was very bad farmers were advised to grow oats, not to cut the crop for hay, but to strip it as the best method of combating take-all. He asked, "Would poverty of soil be a reason for take-all being bad?" Mr. Griffiths said it did not seem to make much difference whether the oats were grazed, cut, or stripped. Oats were almost immune from take-all, and when sown always had a beneficial effect on the soil and a check to take-all. There was no doubt poverty of soil did help. In the north where the ground was stronger there never had been take-all to the same extent as in the Murray Mallee. Mr. B. Flint asked if fallow should be worked dry to destroy weeds. The speaker said it was not advisable to work fallow dry, but if it must be done to kill rubbish work shallow and it would not do a great deal of harm. Mr. B. Flint was also advised that rye grass was practically immune to take-all. Mr. J. Pengilly asked if fallowing with a disc plough disturbed the under layers

of soil and prevented making a good seedbed. Mr. Griffiths said the modern disc plough had very wide wheels, and it was possible to make a good seedbed, but it could not be compared with the mouldboard plough. Replies to the following questions were also given by Mr. Griffiths:—Most combines had narrow shares, was there not a tendency to bring up too much of the underneath soil and spoil the fallow when worked with this implement? *Answer:* The spring-tine cultivator was not entirely satisfactory for fallow working in the Mallee, owing to the tines being strained by stumps causing irregular depth, and if the ground was hard they “cocked up” and ran on the points. In 1916-17 there were small patches of take-all through the crop, and a thistle was nearly always growing in the centre. This was always taken as a sign that there was take-all. If wheat was grown again next year the patch would be bigger, and continue to increase in size until oats were grown or fallowed. *Answer:* Thistles were not a sign of take-all; all sorts of rubbish would be found growing on those bare patches. Is stinkwort likely to become a nuisance in the district? *Answer:* There was no need to fear that stinkwort would become a nuisance as it was in districts of higher rainfall; up to 20in. of rain a year. Would the heavy rainfall of last year have anything to do with take-all? *Answer:* Undoubtedly the frequent light rains of last year encouraged the roots to keep near the surface, and therefore weakened their resistance to disease. Does drake grow in the scrub? *Answer:* It was possible for small plants of drake to grow in the scrub and infest ground when it was cleared. (Secretary, J. Pengilly.)

Competitors in the 1934 River Murray Fencing Championships.

April 13th.—Attendance, 8.

A REVIEW OF THE PAST SEASON.—Paper read by the Hon. Secretary, Mr. W. Trestrail:—“The year 1933 will long be remembered by the farmers of this district as one of the worst years in our history of farming. The year opened full of promise and continued so until the middle of September, when hot, dry weather set in and ended all prospects of a good harvest. The season opened early in April, when a big thunderstorm broke over the district, and on many farms over an inch of rain fell in less than an hour. This rain was followed with good rains the following week, and thus enabled the land to be prepared and weeds killed in good weather. April’s rainfall was 188 points. May was also a good month, and 251 points were recorded. June was much drier, with only 58 points. July was fair with 110 points. August was very good, 254 points being recorded. September also promised, well over 2in. were gauged. October only yielded 34 points. November 56 and December 30 points—12.49 for the year. Thus 10in. was the amount of useful rainfall for crop purposes. The weather in October and November was very hot and dry, at times with frosts that spoilt many promising crops. We started working the land about the middle of April, using the sundereut, and turned over 60 acres of grass land that had not been cropped for about five years. This was harrowed later and cleaned up and sown on May 5th with Algerian oats at the rate of approximately 50lbs. seed and 75lbs. 45 per cent. super per acre. From this piece we cut 40 tons of hay and reaped 296 bags oats. For the dry season this yield was a very satisfactory return. We next worked up

with the disc 30 acres and sowed Free Gallipoli wheat, 60lbs. wet pickled seed and 75lbs. super, sowed with combine on June 9th. This was on old ground similar to the land where the oats were sown. This piece yielded about 12bush. an acre. We then proceeded to get to work on our fallow, which, owing to the rough nature of the land with stone and mallee shoots, we had to deal very carefully. A lot of labour was spent in clearing away bush that had grown up. The combine went over the ground twice and made a fairly good job of killing the weeds and grass. Twenty-seven acres of Free Gallipoli were sown with the combine on June 15th to 17th at the same rate as the previous piece, and this lot yielded 10bush. an acre. This wheat seems a good doer, and can stand a long, dry spell fairly well. We next sowed 75 acres of Nabawa, dry pickled, on July 3rd, finishing on the 21st. The piece was divided into two lands, and that which was sown first gave better yields. The rate of sowing was 70lbs. seed and 90lbs. super. The returns were very light. The whole piece yielding an average of 3bush. The frost seemed to be a factor in reducing the yield. The piece sown later never did at all well, owing principally to the dry conditions and heavy stony soil. Eight acres of Sultan were sown last, but the rabbits ate the biggest portion of this plot, and we only reaped about 8 bags from the plot. Our whole wheat yield thus was approximately 6bush. an acre. The lowest for many years. No disease was noticed in the wheat crop. The oats had a little loose smut. Some patches of wheat in the stony soils died right off in November for want of rain. The rain registrations are those recorded in our own gauge on the farm''.

● FULL MOON.

breeze, because the slow burn will kill more stumps. Following this is the stubble burn. If the stubble the first year is not thick enough for a running burn I prefer logging it first before fire raking; it makes a far more satisfactory job, and this can be done when it is too cool to burn. By dragging it with a full fire rake it makes a satisfactory job. If there is not much fire raking to do, March is an ideal month to kill shoots, and even if they do shoot again the heavy frosts will give the young, tender shoots a severe shock, killing many of them. The second crop on new land should be oats, and it does not need to be a heavy crop to get a good burn, because oaten stubble burns very readily. Quite frequently in this district when poor crops have resulted the first year or two, the shoots and shrubs make rapid headway. When shoots get to this stage, say, 2 or 3 years old, there is only one remedy for them, and that is a sundercut, being unequalled for rough country. This should be done after seeding, the earlier the better, and what shoots are not dragged off with the discs can be cut with a slasher. The next process is the cleaning up of shoots, spinifex, and other growth. For this a scrub rake makes a clean job, besides pulling out loose stumps, etc., and acts as harrows to the soil. After raking the rubbish into rows it can be raked into heaps and burnt. This makes a reasonably clean job, and then it can be left until autumn rains, when a bridle draught cultivator can be worked with ease, and it will be astounding the amount of stumps that are pulled out which were loosened by the sundercut. Worked over twice with the cultivator it is then ready for drilling, and reasonably good crops can be grown on the poorest land with this method. This may seem quite a lot of bother to farmers with large holdings, but if 200 acres less were sown and the extra time put into cleaning up the other more will be gained. Where the shoots are thin, cut and leave them on the stumps, where they can be burnt. If this is done in February or March quite a number will be killed in this manner. A grass fire is very severe on what shoots are left after previous croppings. Finally, if any stumps are left the grubber is the surest remedy."

MYPOLONGA.

June 21st.—Attendance, 80.

The Annual Pruning and Cow Judging Competitions promoted by the Mypolonga Branch of the Agricultural Bureau were held on Thursday, June 21st, and a large number of visitors presented themselves at the luncheon served in the fine shed lent for the occasion by Mr. J. Victory. The newly-elected President of the Bureau (Mr. E. Llewellyn) occupied the chair, and among the visitors were Messrs. T. Playford, M.P., P. H. Suter

Mr. A. Wedd, of Mypolonga, who won the Fruit Tree Section of the River Murray Pruning Competitions.

(District Government Dairy Instructor), F. J. Cawte, M. O'Grady, F. A. Halliday, and F. C. Richards (Assistant Secretary Agricultural Bureau). There was an excellent entry for the Vine and Fruit Tree Pruning Competitions, the successful competitors being:—Vines: 1st, A. Wedd; 2nd, W. Vogt; 3rd, S. Kuchel. Fruit Trees; 1st, A.

Mr. A. Halliday (Judge) with one of the Competitors in the Cow Judging Competitions at Myppolonga.

Myppolonga Pruning Competitions, Competitors at work on the Apricot Trees.

Wedd; 2nd, W. Vogt; and 3rd, C. Rowley. Mr. E. Leishman, of the Department of Agriculture, and Messrs. W. Noles and B. Edson adjudicated. Mr. J. A. Halliday, of Murray Bridge, made the following awards in the cow judging:—Senior: 1st, L. Llewellyn; Suter Cup: 1st, L. Lodge. School boys: 1st, J. Lodge. (Secretary, R. Llewellyn.)

MURRAY BRIDGE (Average annual rainfall, 13.64in.).

April 18th.—Attendance, 31.

[Papers by Students from the High School.]

SELECTION OF DAIRY CATTLE.

[By E. LEHMANN.]

In the selection of a type and breed of cattle suitable for dairy purposes it is advisable to bear in mind the climatic conditions under which the cows have to live and produce. If the climate is cold and wet and shelter scarce, the light-coated, thin-skinned type cannot be expected to do well unless special provision is made to protect

them against adverse weather. If the cost of providing proper shelter is likely to be expensive, select a type and breed noted for robust constitution. The heavy-coated, thick-skinned, fleshy breeds are better adapted for cold and wet conditions than the lighter-fleshed, thin-coated types. A very strong constitution is required to withstand cold weather, and to combat the many ailments and diseases that high-producing cows are subjected to. Another important factor to be considered in the selection of dairy cattle is fodder supplies. If the natural or prepared pasture is not abundant, and the dairyman has to resort largely to handfeeding, it would not be profitable to select a breed and type requiring large quantities of fodder; present prices of dairy produce will not permit much labour cost in the production of fodder supplies. Profitable results can only be obtained where the supply of fodder exceeds the requirements of the cow's system, thus enabling her to turn the surplus into milk. If the supply of fodder is just sufficient to satisfy the requirements of the body, there cannot be a supply of milk unless produced at the expense of the cow's system, which will, in the course of a short period, ruin the cow and the dairyman also. I have observed throughout our swamp areas and the districts surrounding Murray Bridge, including the Hills district, that quite a number of dairymen have cattle totally unsuitable for the general conditions under which they are living. I have noticed Friesians and Shorthorns in parts of the district where the pasture is suitable only for sheep. Very little additional fodder is supplied, with the result that the milk supply can only be disappointing and unprofitable. Under such conditions the breed would probably be condemned because of the owners' lack of forethought. I have also noticed in places where pasture is plentiful a type of cattle whose lack of capacity for the consumption of fodder is better suited to those districts where the pasture is less plentiful. *Type of Cow Likely to be a Profitable Producer.*—Commencing at the head, the eye should be large and docile, indicating a good, quiet temperament; the forehead broad, the nostrils large—a sign of good lungs; the muzzle broad, as this is the medium through which the fodder has to be gathered; the jaws should be strong and the horns of medium length, neither coarse nor weak; the neck should be of nice length, well set on the shoulders and head, but should not show heaviness in the brisket—a very light, weak neck is generally a sign of lack of constitution. The shoulders should be deep and moderately fine at the top. Looking down over the shoulders they should widen out in the form of a wedge; the girth and foreribs should be nicely sprung to allow plenty of heart and lung room. The back ribs should also be nicely sprung without being barrel-like; the stomach should not be carried high, but should be wide and deep, showing plenty of capacity for the storage of food; the body or middle piece of the cow should be of good length. A cow which has a round barrel-like body has a tendency to bloat, and generally is not a good producer. The back should be level, and gradually widen to the hip bones; the hips wide and level. A nice, even top line is desirable, but is not essential for good production, but adds to the appearance, and denotes excellent formation. The hindquarter should be lengthy from hip to pin bone; this has an influence on the length of the udder attachment; the pelvis wide, and the thurl bones prominent to permit ease in calving, and to give sufficient spread to the hind legs, thus allowing plenty of udder room between the thighs. The tail setting should be high rather than low, and the tail fine and long. The thighs should be lean and uncurving without any indication of beefiness; the hocks should be fine and strong, and not turn inwards, as this is a bad fault which usually accompanies poor udder capacity. Nicely balanced udders are rather rare, but the ideal type looked for commences high between the thighs, gradually curving outwards, and getting broader as it lowers, coming well down between the hocks and then curving and running forward and joining the under line of the body well forward; the teats should be nicely spaced, hang squarely, and be of sufficient size to enable easy milking. Running forward from the front of the udder, large milk veins should be noticed extending well forward, and where entering the body prominent milk wells should be observed. These veins convey the passage of blood from the udder to the heart. Finally, the skin is an indication of the quality of the animal, and should be fine and loose on the fore ribs, which denotes a good circulation of blood. The side view of the cow should be of wedge shape from the forequarters to the rear, and from the top of the back downwards, and from the front to the rear. It is difficult to find cattle embodying all the features sought for in the true dairy type, but it is what each breeder and dairyman should strive hard to obtain, and by careful selection of the dam and sire best results can only be obtained. In conclusion, I wish to emphasise the need for selecting pure-bred stock, giving strict attention to the production performance of the sires' and dams' ancestors, bearing in mind never to purchase stock lacking a good strong constitution. My observations at various cattle shows have given me the impression that many dairy cattle judges and breeders favor too greatly the very fine type of dairy cow, a type too fine to have the necessary constitution to bear the dual strain upon their systems of high butterfat production and the healthy development of their progeny, with the result that both are impoverished, and become the subjects of ailments and diseases.

SHAPING OF FRUIT TREES.

[By L. LUHRS.]

The shape of the tree varies with local practice. In Australia the usual shape is that known as "inverted cone" type. The reason being that the tree must be open, the limbs evenly spaced, and the amount of foliage on them even, and also by doing this the crop produced is spread evenly over the tree, and it simplifies harvesting, spraying, and pruning operations. The type of tree from the nursery is either one straight stick or weak branches on it, or ones with stronger laterals which can be used as the main arms; this tree gains a year by this. On planting, the roots are trimmed of all broken members or any interlacing ones. The single stick is cut back to a suitable wood bud about 15in. to 18in. from the ground. This varies according to the type of tree. Tall growers have a shorter butt, and the shorter growers have a longer butt. During the first summer all unsuitable growths are removed, and then in the next winter the main arms are set in, usually three or five, according to the district. In the following winter the main arms are subdivided and secondary arms set in. This is done each year until the tree is sufficiently strong to bear some fruit. Then leave some fruiting wood on the lower part of the tree, and bring that part into bearing as the top part is still growing. The usual number of secondary arms for good districts

Salisbury.****DELIVERY.**—CHICKS—July to September.
EGGS—July to September.

Intending breeders should recognise the importance of establishing their flocks with only the very best of stock also, pay particular care to the size of the egg. The future of the poultry industry in South Australia is almost entirely dependent on the export trade; the size of the egg for export is of the greatest importance. The breeding stock at Parafield is carefully selected and every egg set or sold is of a minimum weight of 2ozs., and a large percentage considerably over.

All Eggs and Chickens sold from Parafield Poultry Station are guaranteed to be produced at Parafield.

EARLY BOOKING IS ADVISABLE.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Flinders Street, Adelaide.

C. F. ANDERSON, Poultry Expert.

is about 20, but in poorer districts 12-15. If one arm is much taller than the others nip out the terminal bud; keep doing this until the others have caught up. When pruning make use of the fact that if the cut is made close to the bud the new shoot grows nearly in the same direction as before, but if the cut is well above the bud the shoot grows at right angles to the old stem. If the prevailing winds are always from the same direction, grow the tree in that direction so that it will not lean over with the continual force of the wind.

NATURAL AND SEEDED PASTURES.

[By F. BULLER.]

By a natural pasture is meant one which is composed of native grasses; a native grass being one found naturally in the location. A seeded pasture is one which has been established artificially, and may include either native or introduced grasses or fodder plants. Natural pastures are generally found on rougher and hilly country, and where erosion is serious or in the Northern pastoral areas where great distances and low carrying capacity prohibit cultivation. In the Northern Districts Mitchell Grass and Spear Grass, and Salt Bush, &c., are probably the most important. The practice of seeding a pasture is confined to better rainfall districts, which permit a wider range and better type of grass. Good seed and thorough ground preparation are required for the establishment of seeded pastures. The seed should be of distinctly perennial strain and, if possible, procure "mother seed." A seeded pasture can be one of two types—either temporary or permanent. A temporary pasture is one which is intended to yield green feed at some particular season. It can be used to rest or improve regular cereal or other cropped land, or breaking in new lands such as blackberry or bracken. A temporary pasture's duration is usually a short one, about one to four years. Suitable plants are:—Rye Grass, White Clover, Cocksfoot, Wallaby Grasses, Subterranean and Red Clover in conditions which suit them. The land preparation for temporary pastures is not generally as elaborate as for long rotation pastures. These are grown on land which is fit for cultivation. It is not often that a farmer wants to keep good arable land under pasture all the time, but he may put down grasses for 10-12 years until they deteriorate, then plough them up and sow with cereals for a year or two, when another pasture is put down. This process constitutes long rotation pasture. Permanent pastures are seen chiefly in poor scrub lands which are too rough to cultivate. To grow long rotation pastures the land must be well drained, as inferior plants take control if seeded pastures are slow. The seedbed must be firm and free from weeds. Fallowing is the best method of getting a firm seedbed if the land is not too valuable. A roller should be used to break down clods, and follow with cultivator and harrows. The seeding of permanent pastures must be shallow and even. To accomplish this cross drilling can be used. Sow thinly with drill or broadcast. Cover the seed by using light harrows or roll to consolidate, and loosen surface with harrows after. The land should not be too wet. A clean seedbed will avoid the use of a nurse crop. If a nurse crop is necessary use wheat or barley with thin seeding, and varieties not likely to lodge. Autumn sowing is probably best if it can be done early enough to give plants a fair start before the cold weather. Spring sowing is all right if it is not followed too closely by hot winds. It is probably best to sow heavy land in autumn, as it would take some time to work it into condition for spring sowing. For manuring use not less than 56 lbs. to 84lbs. of super per acre sown with the seed. Five hints dealing with the after treatment of seeded pastures:—(1) Do not allow too much growth to go unchecked in young pasture, as ranker growth shades the smaller. (2) Cut rather than graze in first year. (3) If grazing is necessary, cattle are preferable to sheep (method of eating—sheep tug grasses). (4) Prevent from seeding by grazing or cutting. (5) Top dress annually with super, harrow, and lime. (Secretary, F. Gurr.)

May 24th.—Attendance, 16.

GENERAL FARM MANAGEMENT.—Mr. R. L. Griffiths (District Instructor) in speaking on this subject considered that there was no more important subject than this at the present time. He defined efficient management as the ability of a farmer in each industry to show the maximum credit balance between production and expenditure. In many cases, however, the management was taken out of the hands of the farmer. He thought that that was one of the factors influencing many farmers at the present time. In dealing with wheat growing he found difficulty in giving advice because of the poor prospects of making a success in this direction in the low rainfall areas. He quoted from the costing figures published in recent numbers of the *Journal* and used statistics to illustrate how difficult it was to make a success of wheat farming in the mallee areas with wheat at 2s. per bushel. He showed that 40 per cent. of the cost of production was for interest and depreciation. With improved prices for wool there was added interest in sheep grazing. Mr. Griffiths considered that sheep should be classed as a main industry in the mallee area, and not a side-line. The best managers always realised that and in some cases classed sheep as the more important. Quite a number

attempted to make a success as dealers. There were a few men who were born dealers and to most farmers there was little hope of making success in that direction, mainly because they could not keep in close touch with market conditions. The speaker suggested that a permanent flock should be built up; provision made for hand feeding in dry season and storage of surplus feed when it was plentiful. He gave details of the different breeds and methods of storing ensilage. *Sidelines*.—The lecturer gave details of management in connection with dairy cattle, pigs, and poultry. He showed that it was practically impossible to make cows pay in the low rainfall districts, but was most optimistic when referring to pig raising. His details of the experiments at Parafield in the feeding of poultry proved very interesting. In all cases he stressed the importance of good stock and scientific feeding. (Secretary, F. Burr.

SOUTH AND HILLS DISTRICT.

CLARENDON (Average annual rainfall, 32.89in.).

March 26th.—Attendance, 11.

[*Papers contributed by young members of the Branch.*]

POULTRY (Mr. M. Harper):—"Poultry farming in a big way, and worked with system, method, and a scientific knowledge of its requirements, has enabled this industry to become one of our most stable primary products. Knowledge, if only in an elementary form, may spell success to the beginner. He must be a keen listener and also an observer. He may know a book of knowledge, yet lack a few essential points which may mean pounds of loss, or an inferior flock of birds, although he may have started with highly productive ones. If egg production is the object, keep White Leghorns or Black Orpingtons. The Whites are good layers and lay a large egg; the Blacks generally lay when eggs are a good price. Opinion differs widely concerning the best breeds for the table. Orpingtons are much in favour, or a Leghorn-Orpington cross makes a very good table bird. *Housing*.—Have plenty of room. Face the house east or north-east to catch the morning sun. There are too many draughts and too much driving rain from other directions. Avoid low houses—they are a nuisance when working in the shed. I suggest 7ft. high in front and 5ft. 6in. or 6ft. at the back. There should be plenty of chaff and litter on the floor. This provides a good scratching ground. The wheat could be scattered among this. A fowl that will not scratch for her food is not much good. Perches should be of 2in. x 1in. wood, laid on the flat, and should be movable to make cleaning out easier. They should be from 18in. to 2ft. off the ground. Keep all joints of woodwork free from vermin by pouring in a little oil and kerosene occasionally. *Feeding*.—Laying hens should have a warm mash in the morning—50 per cent. bran and pollard (two-thirds pollard and one-third bran), the other 50 per cent. being chaffed greenfeed. They should also have chaffed greenfeed again at noon and wheat at night (about 1½ozs. to 2ozs. per bird). Be sure and keep a good supply of clean drinking water. This should be given at least once a day. Keep it in the shade. Much sickness and loss of birds are due to drinking water which has been heated by the sun. They should also have plenty of shellgrit. This can be placed in the nests—it keeps the eggs cleaner than straw and does not harbour vermin. Nests can be made by cutting kerosene tins on the flat. Culling is necessary. At least once a year go through the flock and get rid of any old birds and any that are inclined to go broody unless you wish to set her. Twelve pullets will lay as many eggs in a year as 17 hens two years old, and as many as 24 three-year-old hens, so that it is necessary to place rings on the birds to distinguish their ages."

THE SHEEP AND ITS PRODUCTS (Mr. J. Langeford).—"Sheep are classed into long-wools and short-wools. The production of clean wool is no greater under a full diet than one which simply maintains the condition of the sheep. Indeed, a sheep may lose somewhat in live weight without much effect on the wool production; but with a starvation diet the yield is seriously diminished. If the wool grows half an inch in the first three months it will grow half an inch in the last three. Poor pasture is shown

by the thickness of the wool. Poor pasture causes the break in the fleece, and affects the price of the clip. Environment, climate, pasturage, and breeding exert considerable influence on the productive powers and consequently on the character and type of wool the sheep produces, and are the chief causes of much variability in wool growth, whose commercial values are so various as to necessitate the classing of wool. The fleeces of a small clip are almost as variable in type and condition as those of large clips, so that to give full value it is essential that small clips be graded for market as well as large ones, but not so extensively. The number of fleece lines will be reduced to suit the clip being classed. Some of the chief factors affecting methods of classification are climate, size of flock, type of wool, conditions. Hence, definite methods for classing of small clips cannot be given. In connection with them it is best that the common sense principle of uniform matching of wool be adopted, as classing cannot be effected with such perfect regularity as large clips. Each of the classes required should be made uniform and the lots as big as the number of sheep will permit. Mixed fleeces must be classed according to breeding and type. Sound back fleece wool is typed higher, sells more readily, and a better average price per pound is obtained. *Classing*.—The following are the lines into which such a clip would probably be divided, with a description of the wools to be found therein:—Fleece wool—AA: sound, good length, light condition, 64's upwards; A: sound, shorter, heavier, 64's upwards; BB: sound, good length, light, medium condition, 60's; B: sound, shorter, heavier, 60's; C: short, fatty or tender. In some seasons the number of tender fleeces may necessitate the making of a separate line branded 'Fle' or even two lines. A Fle.: the finer condition fleeces; B Fle.: the broader tender fleeces. *Skirtings*.—A Pcs.: the longest and lightest pieces; Pcs.: shorter and heavier; Bls.: probably one line of bellies, minus stains; Bks.: the earthy backs; Std. Pcs.: one line minus dags; Lks.: one line minus dags. It is a very bad policy to allow dags and fribby ends to be included in a bale of locks or stained pieces, as the buyers do not pay for these, while the freight must be paid." (Secretary, T. B. Brooks.)

INMAN VALLEY (Average annual rainfall, 26 to 27ins.).

May 17th.—Attendance, 7.

THE FOX.—Paper contributed by Mr. H. Lewis:—"The fox is an inhabitant of the following countries:—North America, Europe, Asia, Africa, and Australia. The red fox was unknown in America previous to 1760 at which time a number of them were imported from England and landed at Long Island for hunting purposes. They were first landed in Australia in the 17th century by direct importation from England by the Melbourne Hunt Club and let loose in Victoria for hunting purposes. They have extended to their present numbers from that time, until they are a menace to all States which are breeding lambs. During the last 30 years they have spread with great rapidity through South Australia. Contrary to popular opinion the Australian fox is no larger than its English forefathers and is considerably smaller than the foxes of Northern Europe. The fox has one litter per year of 5 or 6 up to 10 which is born blind and remain so for 8 days, suckles for about a month, comes to maturity from 18 months to 2 years and lives to an age of 12 to 14 years. *Poisoning of Foxes*.—When laying baits of meat or dosing a carcass it should not be near a roadway where drovers may be travelling. There are many types of baits that can be used. I prefer parrots; most dogs do not like the smell and consequently there is less risk of losing same, if a bait should be moved by a fox. When laying baits use a drag that has a strong smell near any places likely to be frequented by such as a solitary rush or tree in an open flat. Baits are better laid in pairs for a fox when not hungry and unable to carry two parrots is likely to eat one and carry the other away. Strychnine powder and bicarbonate of soda make the best and quickest poison to use. If fat is used a good mixture can be made by using 6lbs. of fat or dripping with a ½oz. of strychnine with sufficient soda. Boil fat and mix in ingredients and cut into blocks before cold. When using parrots, poison the head as well as the body, for a fox will often eat the head and carry the body away, and thus a good skin will be lost. I am not altogether in favour of traps unless they hold their catches. If a fox loses a paw he is not so active and is then very hard to poison. I am in possession of a vixen which I ran down last season and having heard they make good decoys intend to try and trap or lay baits around it. Strychnine crystals do not dissolve when placed in birds or meat and they are not soluble in water; only in vinegar. For this reason I favour the powdered form. Of the fox, Prof. Wood Jones says, "From a zoological point of view the fox probably represents the most baneful disturbing influence brought about by human folly in introducing an animal into a new country." (Secretary, W. Mayfield.)

KUITPO.

May 2nd.—Attendance, 9.

CALF REARING.—In the course of an address on this subject Mr. R. Morris said the cow should be dried off six or eight weeks prior to coming in again. That was not always simple, especially in the spring, when feed was good, although, as a rule, it

was more difficult to keep up the supply of milk. In two instances Mr. Morris had experienced trouble in drying off cows and had washed, and after disinfecting the teats, applied Stockholm tar to seal them and prevent the penetration of germs. That was quite effective and could be recommended. When the calf was born it should be left with the cow for 24 hours; at the end of that time the cow should be drenched. Mr. Morris did not recommend drenching prior to calving; it had a tendency to upset the cow. The calf should be put out of sight in good, clean accommodation, with access to sun and light. When the cow was first milked it was easy to tell which quarters the calf had sucked, and if any were weak it was a good plan to put the calf on them again to stimulate the flow of milk. The calves were best kept separate to prevent sucking one another. Mr. Morris attributed one cow he had with "pea teat" to that habit when young. The most important period for feeding a calf was the first six months, and it was during that time that one built up a good or indifferent producer. The first week, as the cow's milk was not of much value, feed 4 pints of fresh milk twice a day. The second week 3 pints of fresh and 2 pints separated twice a day; the third week 2 pints fresh and 3 or 4 pints separated and some hay. The fourth week the same amount fresh and more separated, the fifth and sixth weeks increase the amount of separated milk. After that give separated milk with a little fresh, the fresh milk being a preventive of scouring. A good cure for scours was to feed the calf on fresh milk and add 2 tablespoons of flour with milk. Mr. Morris spoke of the old practice of placing a hot iron in the milk to be fed to calves as being a quick way of heating up the milk to the desired temperature. The calf should never be fed on frothy milk, and at three to six months could be weaned and run in the paddock and watched to see how it developed. It was best to have a good breed of animal, but the most important thing was feeding. Mr. Morris spoke of the teat feeding of calves as being more natural than the bucket, but harder to keep clean and free from germs. He could not recommend a substitute for milk, and the cost of feeding on milk was not very expensive, the first week costing 3s. 6d., the second and third 2s. 7½d. per week, the third, fourth, and fifth at 1s. 9d. per week, and it was worth while, even though all calves do not turn out good. Questions were asked and a discussion held on various points of the talk. (Secretary, J. Pickup.)

MOUNT COMPASS

ANNUAL MEETING.—There was no exception to the rule of large attendances of the Mount Compass Bureau when the members held their annual meeting and social on June 7th. The committee had prepared a varied programme of musical items and short addresses by visitors and Departmental officers. Mr. A. Kidman presided, and besides representatives of neighbouring Branches, there were present Messrs. Jos. Johnson, H. C. Pritchard (General Secretary), H. H. Orchard (Horticultural Instructor), and members of the Mount Compass Branch and their friends. Mr. Kidman reported that the average attendance of members and visitors for the 12 meetings held during the year was 46. Addresses had been given by Miss Campbell (Education Department), and Messrs. Ford on "Banking," Nottage on "Experiences in Africa," R. Hill (Agricultural Instructor), Muller of Myponga, C. F. Anderson (Poultry Expert), Dr. Callaghan and R. Baker (Roseworthy College), E. Leishman (Horticultural Instructor), and K. Verco. Field days had been held on the farms of Messrs. Dowells, A. Peters, M. Jacobs, and Hunt. Special reference was made to the successes of Mr. C. E. Verco who had beaten his own State record with one of his young cows, and Mr. Howard Peters who was second in the Meadow Hay Competition, Mr. Peters, sen., being a close runner up. Since December sheep and lambs from the district had topped the Adelaide market on six occasions.

The work of the Secretary (Mr. C. E. Verco) had been highly appreciated during the year. After pointing out that all the successful people of the district were members of the Bureau, Mr. Kidman made a special appeal to others to join the Branch as they had "everything to gain and nothing to lose" by becoming active members.

There was increased interest in the Junior Potato Growing Competition, and Mr. Jos. Johnson, of Adelaide, presented a trophy to Don McKinlay who grew 278lbs. of potatoes from 1lb. of seed. The rules of the competition provided that each school boy candidate was required to cut and plant the sets in the presence of not less than two stewards. In all other respects the candidate was allowed to have whatever assistance he desired. The potatoes were dug in the presence of not less than two stewards on the Tuesday preceding the Mount Compass Show, at which all entries were exhibited. Competitors were also divided into two teams (selected before the potatoes were planted) and a prize was given to the team growing the greatest quantity of tubers. Tom Garden's team won this competition by 11lbs. in the weight of tubers dug. As this team was one boy short, it was given an allowance of a pre-arranged weight.

The variety of potato grown was Carmen, and the seed potatoes were donated by Mr. Johnson. The following were the results:—

Team.	Sets Planted.	Crop from 1lb. Seed. Dug. Weight in Lbs.
Tom Garden (captain)	44	41 198½
Linton Jacobs	51	38 268
Noel Jacobs	57	50 230
Arthur Stone	47	40 124½
Kelvin Peters	31	28 151½
Sam Miller	39	37 87
Ray Chigwidden	57	57 181½
Harry Garden	29	14 66½
Ronald Lane	37	19 27
Alex Anderson	50	48 186
Team.		
Don McKinlay (captain)	39	39 278
Norman Anderson	53	53 196
Ben Peters	38	37 166
Ray Richardson	31	31 58
Ross Williamson	59	59 180
Stanley Hales	55	45 78
Ralph Cole	37	37 119

Douglas Chigwidden	49	48 192
Laurence Garden	53	50 193
Bob Richardson	22	21 35

The winner (Don McKinlay) first of all dug the plot in which the seed was planted; it was then hoed two or three times and again dug. He applied bone and blood manure and super as well as general farmyard manure. The distance between the sets was 2ft. 6in. x 2ft. 6in. Linton Jacobs dug his plot one month before planting 3ft. between sets and used a bucket of super, sulphate of ammonia, and three bags

of fowl manure. Noel Jacobs ploughed and cultivated the plot several times and applied $\frac{1}{2}$ wt. super, $\frac{1}{2}$ wt. bone and blood manure, and five bags of fowl manure; distance between sets. 3ft. x 5ft.

After congratulating the winners on their success, Mr. Johnson gave a short address on growing potatoes.

In the Flower Competition (for girls), the first prize was won by Miss Ronda Peters, the other competitors being Naomi Dowell, Jeyce Chigwidden, Elizabeth Jacobs, Joan Dowell, Thelma Anderson, Mavis Anderson, Pris. Miller, Emma Haywood, Ruth Dowell, Nellie Peters. Seedlings for this competition were supplied to each competitor and the blooms were judged prior to the show.

Mr. Pritchard presented the trophy to the winner and spoke on the value of competitions in the work of the Agricultural Bureau.

The musical programme was presented by Mrs. Wundersitz, Mrs. Rumbelow, Miss Wundersitz, and Messrs. Rumbelow and Solly.

The Chairman announced the election of officers for the coming year as follows:—Messrs. A. Kidman (President), H. B. Peters (Vice-President), C. E. Verec (Secretary), J. Sneyd, S. Eckers, W. Hunt, B. Proctor, and W. Jacobs (Committee).

NARRUNG.

April 14th.

MANAGEMENT OF LUCERNE AND DAIRY COWS.—Paper read by Mr. E. Wyatt:—"The first essential in sowing lucerne is to have the ground well worked. Harrow the ground down well so that there are no air pockets. The seed can be sown on rolled ground. I prefer broadcasting the seed after the land has been sown with $\frac{1}{2}$ bush. of barley and 60lbs. of super to the acre. Do not be afraid of burying the seed too deeply. I have had better results by harrowing two or three times than by only brushing it in with a bush. If the plants germinate and are too near the surface a dry spell may be experienced, and in this district it may kill the plants. If it is well harrowed in it is able to withstand any dry spells that may come along. My reason for sowing barley is that it comes off much earlier, and gives the plant a better chance to establish itself. The barley should be cut when it comes out in ear, preferably for ensilage; with the lucerne and undergrowth it makes splendid ensilage. If this cannot be done early, then the barley should be stripped and the straw left to protect the young plants, for when they are exposed to the hot sun and hot ground they very often get burned off. The lucerne should be grazed very lightly the first year, this will give it a chance to stool, but it can be cut if it grows well enough.

The year after sowing, topdress with 3wt. of super to the acre, and sow $\frac{1}{2}$ bush. of oats. This should be done with a hoe drill so that the plants will not be unduly injured. The oats should be of an early variety, and should be grazed when 4in. to 6in. high, then left and cut with the lucerne when the oats are coming out in ear, for loose hay. Graze or cut the lucerne the next summer; the following winter the plant should be well established. The following year it is supered again. On 'oily' ground in this district it is difficult to establish lucerne, but the trouble can be overcome by working the ground with as much grass and rubbish in it as possible. Work it with a cultivator or combine, and leave it in rows as left by the machine. When a suitable rain comes—and it must be a good rain—soak the lucerne seed for three or four days, and mix with barley, sowing at the rate of 5lbs. to 6lbs. lucerne to the acre and $\frac{1}{2}$ bush. of barley; this mixture to be broadcasted, then brushed in, but not harrowed. The seed collects in the gutters, the lowest part of which is wet, the seed germinates quickly, and each shower waters it as the water collects where it is most needed around the plant. It should then be handled under ordinary conditions. Fifteen to 20 acres of lucerne should be put down each year so that a fairly young stand is maintained. The young stands grow much better through summer than the old ones, and provide much more feed at a time when it is wanted. The main secret of having lucerne right through summer is not to have 40 cows and 80 acres, it is much better to have 10 cows and 80 acres. There should be six acres of lucerne at various stages of age to every cow kept. Another important point is letting the cows graze it according to the rate it is growing. They should be 'minded' on large paddocks when it is getting scarce, and kept from roaming all over it. An hour a day will give them a good fill of lucerne if it is a good length. To get the most out of cows they need a big variety of feed and plenty of it. This variety of feed should be put aside in times of plenty in the form of ensilage, lucerne hay, mixed hay, that is hay made from lucerne, grasses, and barley or oats, oaten hay, to be cut into chaff. The ensilage and loose hays can be obtained if the paddocks are worked as mentioned. If put in early oats very seldom fail to provide a good hay crop in this district; the chaff keeps the cows in good heart and condition through the slack times and early winter. At present (April 4th) my herd is having a little bran in the bails for the best cows. After milking, ensilage and lucerne hay; after dinner, an hour on good lucerne; after milking at night, more hay. I believe in feeding fresh cows some bran at this time of the year, so that they will hold at their production until the feed

is strong enough to support them. At present there are four cows 'fresh in,' averaging over 60lbs. of butterfat per month, at 9½d. per pound, they are bringing in £2 8s. per week, and they deserve the 4s. to 5s. worth of bran they receive. If it was not for that their production would soon drop back twice what it costs to keep it up. When the lucerne is beginning to go off, the best substitute is ensilage, even with a fair picking of lucerne about the cows have eaten it up splendidly. Try to work the cows so that they are in watered paddocks during the day and in unwatered paddocks at night. Water should be laid on to every paddock so that they can have it at any time day or night.

Do not turn the cows out in the paddock straight after milking; they should be put in a yard alongside those that are not milked; this keeps those that are not milked more contented and not anxious to get out. No stock whips or sticks should be used on the cows; they should be milked and handled in the yard, and moved about as quietly as possible. Milking should be done as quickly as possible, so that the cows are only in the yard a short time, and it gives them more time for feeding or resting. Never miss milking a cow until she has definitely got to go dry. If by going out some of the stale cows have to miss being milked, then do not go out. Since establishing lucerne on the property, culling the cows severely after testing them, and piping water to nearly every paddock, and providing plenty of fodder for the slack time of the year, the average production of my herd has risen from 187lbs. of butterfat to 369lbs.—nearly double their production—which shows that attention and proper food is worth while." (Secretary, W. Laurie.)

TWEEDVALE (Average annual rainfall, 35.97in.).

April 2nd.—Attendance, 15.

TYPE OF PIG FOR EXPORT AND MANAGEMENT OF PIGS.—Points from an address by Mr. Roy Baker. In opening his address he dealt with the best type for export; there were two carcass types, namely, porker and baconer. England required baconers, Australia, he said, had too many different breeds. *Points of a Bacon Pig.*—The baconer should be lean in the jaw, as head meat is cheap. Light in shoulder, thinness of flesh over the shoulder; length of body was important. Levelness of the back, well let down loin. Depth of side and thickness of belly. Level underneath and level along the back. Well-shaped ham, broad, well let down, and a mass of meat. There were four breeds, namely, Large White, Mid York, Berkshire, and Tamworth. The Large White, he said, was not proving the right pig for export, but was a good sire on either the Berkshire or Mid York; it produced a fine carcass. He also favoured the Tamworth-Berkshire cross. *Feeding of Pigs.*—He stated that there was a 7 per cent. gain by feeding meal; labour of cooking was not warranted. Rough foods, such as potatoes, should be cooked; salt should be added to these when cooking, to improve them. Always feed dry, never soak food fed in conjunction with water; food should be damped, but not be sloppy. Water should be handy at all times. *Exercise.*—Pigs remained healthy if allowed plenty of exercise, digestion was also aided, and a better carcass the result. Pasture for pigs was essential. It also lessened the grain to be fed. If skim milk was fed, it should be fed on a scale of 3lbs. to 5lbs. of milk to 1lb. of grain. If self-feeders were used it was a good plan to have the water trough some distance from the feeder, that caused the pigs to travel, thereby giving them the much required exercise. Pigs should have minerals, the following was advised:—20lbs. charcoal, 20lbs. coarse salt, 40lbs. bone meal, super, or rock sulphate, 5lbs. Epsom salt, 5lbs. bi-carbonate, 5lbs. sulphur, 5lbs. sulphate of iron. The mixture should be used at the rate of 1lb. to 2lbs. to every 100lbs. of grain. *Breeding.*—The boar was half the herd; he should be pure bred, active, of medium size, and should come from a 10 or 12 litter. Legs should be straight outside the body, "down" on the pasterns was a bad fault. Examine the rudimentary teats, he should have 12. The sow should have 12 good teats, well forward, the number of teats had no bearing on the number of pigs she would breed. Dummy teats should be well developed and stand out from the belly. Do not breed until 8 months old, she will then have her first litter at 12 months. Feed the sow well. She should have two litters a year for four or five years. Do not discard old sows, use them as long as possible. Breed the type that was wanted overseas, i.e., the long, lean type of pig that has been properly fed and carries a larger percentage of lean meat. (Secretary, B. Schapel.)

McLAREN FLAT PRUNING COMPETITIONS.

The annual Pruning Competitions conducted under the auspices of the McLaren Flat Branch of the Agricultural Bureau were held on June 16th in Mr. T. Ingoldby's vineyard. Under the supervision of Mr. C. Robertson, the energetic secretary, Mr. P. Wait, and a most efficient committee, the competitions proceeded without a hitch.

The cup presented by the R.A. & H. Society for the highest points in the Vine Section was won by Mr. R. J. Deane.

Eighty-six competitors pruned in the Vine Section this year—a record entry since the McLaren Flat Branch has been responsible for the management of the Competitions. To obtain a certificate of efficiency, a pruner must receive 80 out of a maximum of 100 points.

This year, 153 certificates out of a possible 172 were awarded—striking evidence of the high standard of vine pruning that has been reached by pruners in this Competition. The following table sets out the results:—

TRAY-MOBILE SET.

In reply to a question as to the number of pieces of work in a tray-mobile set, which was submitted by the Clare Branch, Miss E. Campbell (Inspector of Domestic Arts, Education Department) says the full set contains the following pieces:—

1. Two tray cloths (one for upper and one for lower shelf).
2. Tea cosy.
3. Teapot holder.
4. D'oyleys, usually four of assorted shapes and sizes.
5. Small serviettes, usually six.
6. If a teapot mat is used there is usually a cover for the mat to match the rest of the set.

In many shops smaller sets, comprising the tray cloths and two or four d'oyleys, may be purchased ready stamped for working.

WARTS ON COWS' TEATS.

Mr. H. B. Barlow (Chief Dairy Instructor) has advised the Secretary of the Gladstone Women's Branch of the Agricultural Bureau that the cause of warts on cows' teats, although not quite understood, is thought to be at least partly caused by leaving the teats wet, friction, &c.

Warts may clear up spontaneously, but any of the following dressings will assist:—

1. Smearing with castor oil after milking.
 2. Painting with glacial acetic acid on dry teats.
 3. Washing in strong soda solution. This may be done in combination with 1.
- Some authorities state that certain types of warts are contagious.

GOOD THINGS FROM THE OVEN.

[By GRACE B. ARMSTRONG, A. MARIE SCHRIEBER, and MARY A. MCPHER,
of the University of Illinois, Urbana, U.S.A.]

(*Continued from page 1496.*)

Part II.—Recipes and Directions.

PUDDINGS.

CUSTARDS.

Custards are products made of milk thickened with eggs. There are many varieties, but the same general principles for making them hold true for all methods of cooking. They may be steamed, baked, or cooked in a double boiler.

BAKED CUSTARD.

Equipment.

1 mixing bowl	1 tablespoon
1 egg beater	1 shallow pan
1 measuring cup	1 baking dish
1 teaspoon	1 strainer
1 double boiler	

Materials.

2 c. milk	$\frac{1}{2}$ t. salt
2 to 3 eggs	$\frac{1}{2}$ t. vanilla
$\frac{1}{2}$ c. sugar	

Amount: 2 or 3 servings.

Method.

How.

Scald milk.

Beat eggs slightly.

Stir in sugar and salt. Pour scalded milk over them gradually. Add flavouring.

Pour through strainer into baking dish.

Set baking dish in a pan of hot water.

Bake in very slow oven (250°F.) until a knife thrust into the custard comes out clean.

Why.

Scalding will hasten the baking. If saving time is no object, milk need not be scalded.

A smoother, firmer custard results when eggs are beaten but slightly.

Eggs are less apt to coagulate if mixed with sugar before hot milk is added.

Straining removes cord and any coagulated bits.

Hot water keeps the cooking temperature around the custard even and low enough to prevent toughening of the protein.

Too long cooking at too high temperature will cause the custard to separate.

PRUNE WHIP.

Equipment.

1 saucepan	1 strainer
1 mixing bowl	1 mixing spoon or spatula
1 measuring cup	1 tablespoon
1 egg whip	1 baking dish

Materials. $\frac{3}{4}$ lb. prunes $\frac{1}{2}$ c. sugar $\frac{1}{2}$ Tb. lemon juice

5 egg whites

Amount: 6 or 8 servings.

Fig. 3.—Cutting edgewise with a spatula into the middle of the mixture.

Fig. 4.—Sliding the spatula under part of the mixture. (This part is lifted again and folded over towards the centre.)

The cutting and folding motion illustrated with Prune Whip

*Method.**How.*

Look over prunes carefully and discard any not in good condition. Wash and drain in a strainer.

Cook slowly until tender.

Remove stones and rub prunes through a strainer. Return to saucepan. Add sugar and cook 5 minutes. Add lemon juice.

Cool thoroughly.

Beat whites of eggs until stiff.

Carefully cut and fold prune pulp into egg whites.

Slip mixture out of mixing bowl and pile lightly in a buttered baking dish. Do not stir or mix unnecessarily.

Bake 20 minutes in slow oven (300°F.).

Serve hot or cold with cooked custard or cream.

Why.

By using a strainer it is easier to remove any gritty substances.

Slow cooking permits the absorption of water resulting in a plump, full prune.

Mixture should be smooth and of the consistency of medium-thin marmalade or jam.

A cool product will blend with the egg whites more easily.

Air is incorporated into the mixture in this way.

Folding the prunes into the eggs rather than the eggs into the prunes results in less breaking up of the egg.

Careful handling is necessary to avoid breaking up the air cells.

The large amount of egg requires that the mixture be cooked slowly.

Fig. 5.—Date Pudding.

DATE PUDDING.

Equipment.

1 measuring cup
1 mixing bowl
1 teaspoon
1 flour sifter

1 baking pan
1 knife or food chopper
1 egg whip

Materials.

3 eggs
1 c. sugar
2 c. dates
1 c. pastry flour

1 t. baking powder
 $\frac{1}{2}$ t. salt
1 c. chopped nuts

Amount: 14 servings.

Method.

Wash dates and dry on paper or soft cloth. Chop or cut fine with knife. Chop dates and nuts. Sift dry ingredients. Beat yolks until thick; mix with dry ingredients. If mixture seems too stiff, add 1 tablespoon of milk or water. Beat egg whites until stiff, and fold into above mixture.

Bake in large pan 30 minutes in moderate oven (350°F.). Cut into strips for individual servings. Serve with hard sauce or whipped cream.

(HARD SAUCE.)*Equipment.*

1 mixing bowl
1 measuring cup

1 wooden spoon
1 teaspoon

Materials.

$\frac{1}{3}$ c. butter
1 c. powdered sugar

$\frac{1}{3}$ t. lemon extract
 $\frac{2}{3}$ t. vanilla

Amount: 1 cup.

Method.

Cream the butter (butter must be soft and well-worked before it will absorb and hold sugar). Add sugar gradually, working each addition well into the butter before adding more. Add flavourings. When done, hard sauce should resemble medium-soft white butter.

STARCH PUDDINGS.

The thickening, or basis, of the following group of puddings is starch, though many other ingredients may be added. The main principle to consider in their preparation is that of sufficiently swelling and cooking the starch. Long cooking with moist heat is necessary.

ALL TREES HARDENED IN THE OPEN.

RICE PUDDING.

Equipment.

1 double boiler or steamer
1 measuring cup
1 fork

1 teaspoon
1 strainer
1 baking dish

Materials.

$\frac{1}{2}$ c. rice
2 c. water
2 c. milk
 $\frac{1}{2}$ t. cinnamon
2 eggs

1 t. salt
 $\frac{1}{2}$ c. sugar
 $\frac{1}{2}$ c. raisins or currants
1 Tb. butter
Grated rind 1 lemon

Amount: Enough to fill a large casserole.

*Method.**How.*

Carefully wash rice by putting it in a strainer and allowing water to run through it.

Put water and salt in top of double boiler and place directly over the heat. Bring water to boiling point. Gradually add washed rice, stirring with a fork.

Boil 3 to 5 minutes. Then place over underpart of double boiler, in which there is boiling water. Cook for 30 minutes.

Add milk and stir slightly with fork. Cook for 20 minutes longer, or until rice is very soft.

Add melted butter. Beat eggs and add with other ingredients, using a fork to stir them into rice. Put in baking dish; cover with cracker or bread crumbs, and bake in moderate oven (350°F.) until custard is done.

Why.

Unless unpolished rice is used, there is always a talcum powder on the rice, which when cooked causes the grains to stick together and results in a gummy product.

This method prevents the rice from sticking to the pan. A fork does not break the rice grains as does a spoon.

Constant watching to prevent the rice from burning will be unnecessary if a double boiler is used after the rice has started to cook.

Milk is not added until the water is absorbed cause salt heated with milk tends to curdle the milk. To have a well-flavoured product, the rice must absorb the salt. When water is absorbed, the milk may be added safely.

COTTAGE PUDDING.

Equipment.

1 mixing bowl
1 measuring cup,
1 egg beater

1 teaspoon
1 mixing spoon
Muffin pans

Materials.

$\frac{1}{2}$ c. butter
 $\frac{3}{4}$ c. sugar
1 egg
1 c. milk

2 $\frac{1}{2}$ c. flour
4 t. baking powder
 $\frac{1}{2}$ t. salt

Amount: 2 dozen small cup puddings.

Method.

Prepare according to the muffin method for plain cake (*details of which will appear in a later issue*). Serve with lemon or chocolate sauce. This pudding should be eaten as soon as baked, since it is not rich enough to keep it from drying out quickly.

(PUDDING SAUCE.)

Equipment.

1 saucepan	1 teaspoon
1 measuring cup,	1 lemon squeezer
1 tablespoon	

Materials.

½ c. sugar	1½ Tb. lemon juice or
1 c. boiling water	½ t. vanilla
1 Tb. cornstarch or	Few gratings of nutmeg
1½ Tb. flour	Few grains of salt
2 Tb. butter	

Amount: 1½ cups.

Method.

Mix together sugar and cornstarch. Gradually add boiling water, stirring constantly. Boil 10 minutes to cook starch thoroughly. Remove from fire. Add butter and flavourings. Serve hot on puddings or on cakes that serve as puddings.

(CHOCOLATE SAUCE.)

Equipment.

1 saucepan	1 teaspoon
1 measuring cup	1 tablespoon

Materials.

1½ c. water	½ c. cold water
½ c. sugar	Few grains of salt
6 Tb. grated chocolate	½ t. vanilla
1 Tb. cornstarch	

Amount: 2 cups.

Method.

How.

Boil water and sugar 5 minutes.

Mix cornstarch with cold water for thickening.

Add grated chocolate to cornstarch and water; then add all to syrup, pouring slowly and stirring constantly.

Why.

Chocolate blends better in hot syrup than in water.

Mixing with cold water separates the starch particles and prevents formation of lumps when added to a hot mixture.

Adding the chocolate to the hot syrup at the same time as the thickening results in a smooth consistency because the starch acts as binder when the chocolate melts. If not held in place by a binder, the fat in the chocolate would cause it to float on the surface of the syrup; then when the thickening was added there would be an uneven composition.

Boil 10 minutes. Flavour with vanilla and serve hot on ice cream or pudding.

FRUIT TAPIOCA.

Equipment.

1 measuring cup
1 saucepan

1 mixing spoon

Materials.

$\frac{1}{3}$ c. minute tapioca

$1\frac{1}{2}$ c. liquid (fruit juice and boiling water)

Amount: 6 servings.

Method.

Boil the tapioca in the liquid until clear, adding more liquid if necessary. Then add sugar and fruit juice as desired. Cool and serve with cream.

TAPIOCA CREAM.

Equipment.

1 double boiler
1 measuring cup
1 strainer
1 mixing bowl

1 teaspoon
1 mixing spoon
1 fork

Materials.

$\frac{1}{2}$ c. pearl or minute tapioca
2 c. scalded milk
1 t. vanilla

2 eggs
 $\frac{1}{3}$ c. sugar
 $\frac{1}{2}$ t. salt

Amount: 4 servings.

Method.

If pearl tapioca is used, soak in cold water for 1 hour, drain, add to milk and cook in a double boiler until tapioca is transparent. Slightly beat egg yolks and salt. Add half the sugar to the milk and the remainder to the egg yolks. Combine by pouring the hot mixture slowly on the egg mixture. Return to double boiler, and cook until it thickens. Remove from fire, cool slightly, and add stiffly beaten egg whites. Flavour and chill.

FIG TAPIOCA.

Equipment.

1 double boiler
1 measuring cup

1 teaspoon
1 mixing spoon

Materials.

$\frac{1}{3}$ c. minute tapioca
 $\frac{1}{2}$ c. light brown sugar
 $\frac{1}{4}$ t. cinnamon or to taste
 $\frac{1}{2}$ c. nuts

$1\frac{1}{2}$ c. water
 $\frac{1}{2}$ lb. dried figs
 $\frac{1}{2}$ t. vanilla

Amount: 4 servings.

Method.

Mix tapioca, sugar, and water. Boil 10 minutes, add figs and cinnamon, then cook in double boiler 1 hour. Add nuts and vanilla. Serve cold with whipped cream.

CARAMEL PUDDING.

Equipment.

1 saucepan
1 measuring cup

1 tablespoon

Materials.

4 Tb. cornstarch
 $1\frac{1}{2}$ c. boiling water

$1\frac{1}{2}$ c. light brown sugar
 $\frac{1}{2}$ c. nuts

Amount: 3 servings.

Method.

Mix the cornstarch and sugar. Add the boiling water, stirring constantly. Boil about 20 minutes, or until there is no taste of raw starch, stirring constantly. Add nuts. Chill and serve.

FARINA CUSTARD.

Equipment.

1 baking dish	1 teaspoon
1 measuring cup	1 mixing spoon
1 fork	

Materials.

1 c. cold farina	$\frac{1}{2}$ c. sugar
2 c. milk	$\frac{1}{4}$ t. nutmeg
2 eggs	

Amount: 5 or 6 servings.

Method.

Stir the farina and milk together until they are perfectly smooth, then add slightly beaten eggs, sugar, and nutmeg. Bake in moderate oven (350°F.) until firm. Serve either hot or cold with any desired sauce.

INDIAN PUDDING.

Equipment.

1 double boiler	1 teaspoon
1 baking dish	1 mixing spoon
1 measuring cup	1 fork

Materials.

1 qt. milk	$\frac{1}{2}$ c. brown sugar
$\frac{1}{3}$ c. corn meal	$\frac{1}{2}$ t. salt
$\frac{1}{2}$ c. dates	$\frac{1}{2}$ t. ginger
$\frac{1}{2}$ t. cinnamon	1 egg

Amount: 6 or 7 servings.

Method.

Place milk in double boiler and when scalded add the meal moistened with cold water, stirring constantly to avoid lumps. Cook 20 minutes. Turn into baking dish and add remaining ingredients except the egg. Stir well and when the mass has cooled somewhat, stir in the beaten egg. Bake 1 hour in slow oven (300°F.). Serve hot with sauce.

FRUIT CEREAL PUDDING.

Equipment.

1 saucepan	1 knife
1 measuring cup	1 mixing spoon
1 fork	1 baking dish
1 teaspoon	

Materials.

1 $\frac{1}{2}$ c. cereal, before cooked	2 eggs
1 t. cinnamon	$\frac{1}{2}$ c. sugar
1 qt. milk	3 large bananas sliced across
1 $\frac{1}{2}$ c. coffee cream	

Amount: 6 or 7 servings.

Method.

The cereal may be any fine wheat preparation, cooked in boiling salted water. While warm, stir in cinnamon. Allow to cool. Add milk. Add slightly beaten eggs to the mixture, stir in sugar, mix well. Pour into greased baking dish; drop in fruit evenly. Bake in moderate oven (350°F.) 25 minutes. Test as for custard. Serve hot or cold.

A further instalment of Part II. will appear in next issue.

(To be continued.)

Papers Read at Eyre's Peninsula (West), Ceduna, July 4th.**JAM MAKING.**

[By MRS. W. PFEIFFER, O'Loughlin Branch.]

Practically all kinds of fruit are suitable for jam. Some may not be quite so useful on their own, but make a good combination with other kinds of fruit. Where the fruit can be picked from the garden it can be used just at the right stage of ripeness, but when the fruit has to be purchased in cases, especially if it has to travel some distance, it has to be carefully picked over. Any soft fruit should be stewed for immediate use. For best results the fruit should be firm, but just ripe. Better results are obtained from slightly under-ripe fruit than from that which is over-ripe.

For the various kinds of fruit there are different methods of preparation. Apricots should be halved and stoned and then weighed; plums likewise, excepting the Damson. Some plums are easy to stone, but some are not, in which case it is perhaps better to allow the fruit to boil without sugar for a while, and try to skim off the stones that come to the surface. But as this method is very tiresome—standing by the fire, especially on a hot day—it is preferable, if at all possible, to store the fruit before it goes on the fire. It may take longer to prepare, but it does not tire so much. A sharp, stiff knife is necessary; cut around the fruit, then put both hands on it, and twist the hands in opposite directions. One half is then free, and the other is cut as close as possible to the stone with the point of the knife. When accustomed to this method there is less waste than by skimming. These fruits do not need peeling, but any blemishes on the skin should be cut off. With the use of sugar, there are exceptions, but, as a general rule, $\frac{1}{2}$ lb. to 1 lb. of fruit is sufficient, but with figs and several of the berry fruits $\frac{1}{2}$ lb. is quite enough. Do not add water to any jam; it usually means longer boiling to make it set, and thus the colour is often spoilt. I usually add half the amount of sugar; mix it lightly with the fruit, and allow it to stand several hours. Warm the remaining amount of sugar by standing it in the oven, and add it after the jam has boiled about 1 hour. Most fruits, with the exception of quinces, apples, and pears, should be boiled quickly; the latter need long, slow boiling to get the right colour.

A reasonably large vessel is more satisfactory than a small one. If the pan is too small the jam cannot be stirred properly, which may cause it to burn. Always stir off the bottom. A board about 3 in. wide, tapered on one end to use as a handle and left wide at the other end and planed to rid it of splinters, and well scrubbed, is more satisfactory than a wooden spoon. A child's wooden spade is quite good. While the jam is boiling see that it does not burn. It needs most watching until it comes to the boil, and more so when nearly done. When the jam has a glassy, transparent appearance and bubbles start to come and break into a number of little ones, which is called "jellying," it is nearly done. Then it is advisable to take out a little and pour it on to a saucer and allow it to stand in a cool place. If thin skin has formed on it when it has cooled, then the jam is ready. If, however, it is watery, it needs a bit longer boiling. When the jam has cooled off a little put it into bottles, either pickle jars or ordinary bottles with the neck cut off. They should be thoroughly clean and dry. If stood in the oven for a while to warm there is less danger of them cracking when the hot jam is poured in. Fill them right to the brim, as it always contracts a little when it cools. When the jam is well cooled, preferably next day, it should have a nice firm skin. It should be sealed, either paper pasted over it and labelled, or melt pure clean tallow and pour it over. It should be stored in a cool, dark, and dry place. Where storing space has to be considered, put into large jars and perhaps tins. Better results can be obtained from a small lot of jam—say, 10 lbs. or 12 lbs. of fruit—than from a much larger quantity. It can be watched more closely, and it does not have to boil so long, thus preserving the colour.

ROSEWORTHY AGRICULTURAL COLLEGE

AFFILIATED WITH THE UNIVERSITY OF ADELAIDE.

GOVERNING COUNCIL:

A. M. DAWKINS, J.P. (CHAIRMAN)	
F. COLEMAN, J.P.	A. E. V. RICHARDSON, M.A., D.Sc.
L. T. COWAN, B.Sc.	PROF. A. J. PERKINS
D. A. LYALL, ESQ.	W. J. ADEY, ESQ.
H. C. PRITCHARD, A.F.I.A. (SECRETARY)	

PRINCIPAL:

DR. ALLAN R. CALLAGHAN.

A thorough and well-proportioned course of instruction in the theory and practice of General Agriculture, including Viticulture and Oenology, as well as all phases of Livestock Husbandry.

The Diploma Course includes three years of class-room tuition and practical work, and carries the academic distinction of R.D.A.

Excellent opportunities offered for the training of boys of 16 years of age or over. Splendid food and accommodation, hot and cold water. Ample sporting facilities, gymnasium, sports oval, tennis courts, and swimming pool.

FEES.—£50 per annum, which covers board and lodging, instruction, medical fee and dispensary expenses.

SCHOLARSHIPS.—Six scholarships are open for competition annually, each valued at £136 10s.

Write for further particulars, and prospectus, to—

THE PRINCIPAL,

Agricultural College,

ROSEWORTHY.

USES OF COLD MEATS.

[Miss L. KLOEDEN, O'Loughlin Branch.]

It is a problem of most housewives during summer to use up cooked meats, especially when the weather is bad, and all the fresh meat has to be cooked. One soon tires of cold meat for every meal, especially the men on farms. They all look forward to one hot meal a day, so I have chosen some simple ways of making hot dishes from cold cooked meats.

These are some of the different dishes:—Stuffed onions and tomatoes; savoury potatoes; curried mince; potato pie; rissoles; cabbage rolls; hurry scurry; mince omelet.

In stuffed onions and tomatoes, savoury potatoes, the meat has to be minced, adding an onion to taste. Then put mince into a saucepan, adding a little water so that it does not stick to the bottom while cooking. Add seasoning; while this is boiling prepare the tomatoes, onions and potatoes. These should be nice and firm, and the size of a small apple, to get best results. The tops should be cut off and the inside removed with a teaspoon. The inside of the tomato, onion, and potato shells are put into the mince. Arrange the shells in a baking dish, add the mince, and put cap on, then bake slowly until done, which takes from $\frac{1}{2}$ to 1 hour. In savoury potatoes the potatoes must be partly baked before adding the mince. These dishes are served with vegetables and brown gravy, if obtainable.

Mince omelet is a very nice breakfast dish, especially when there is no bacon to serve with the eggs. Mince scraps of meat, onion, and pour into pan, and fry until onion is cooked; then beat up eggs and pour over meat; keep stirring until eggs are cooked. Serve on toast.

Another dish made in a few minutes is called Hurry Scurry. Cut up very fine two big onions, and cut into dice a few slices of bacon. Fry this until lightly browned, then put in the pieces of cut up meat and keep stirring until meat is heated through, then pour off fat and sprinkle enough flour to make a nice gravy. Add enough hot water to the consistency of gravy; this, served with boiled potatoes, is very nice.

Cabbage Rolls.—Take enough outside tender white leaves of the heart as required and boil in a saucepan of water until tender. Boil a little rice, enough as wanted, mince the meat and add onion, salt and pepper to taste, and the boiled rice. Add an egg, then roll in cabbage leaves like sausages, and put into baking dish, and bake in a little butter, basting every little while.

Mashed potatoes served with these dishes are very nice, and it is always wise to keep the gravy from roasting, for gravy served with these dishes improves them immensely.

SOUP MAKING.

[By MRS. D. FAGAN, Assistant Secretary Goode Branch.]

Soup, if made well, can be very wholesome food for adults and children. Most soups are improved by having the stock prepared the day before the soup is required. The fat is more easily removed when the stock is cold. For just ordinary soups, any meat and bones, cooked or uncooked, in fact, any savoury food, if fresh and good, may be used to make stock. Trimmings from joints, remains of cooked meat, vegetables, gravies, bacon rinds, or ham bones can all be used. The water in which the joint has been boiled, can be saved and used to make soup. Save the water from boiled vegetables and mix it with the water in which meat has been boiled, and add either more chopped-up vegetables or split peas. If in a hurry, add a small tin of tomato

soup, or a couple of tablespoons of pea meal, or pea sausage, to the mixed vegetable and meat water. But the mixture must be boiling when the pea meal or pea sausage is added, and brought to the boil again and boiled for ten minutes. The mixture can also be thickened with rice, sago, or corn flour.

Try the following methods:—Usually 1 pint of water is needed for every 1 lb. of meat and bones, and 1 pint over for evaporation during cooking. This extra water may be added by degrees to prevent the stock coming to the boil too quickly. Cut up the meat and chop up the bones small, so that the juices may escape easily. Leave out as much of the fat and skin as possible, put the bones and meat in, and cover with the water in the proper proportion. If you want nice brown soup, the meat may be seared first on a hot pan, and the onions may be well browned also. Add about a cup of water, place on a sharp fire, and stir occasionally till the bottom of the pot is covered with a kind of jelly, then add the rest of the cold water. The meat and bones may be allowed to soak in the cold water for an hour or so to draw the juices, place on the fire, and bring very slowly to the boil. Skim it well before it boils much. A teaspoon of salt added just before it boils makes the scum rise. Take care to remove the scum only, and not the juices, which rise also. Keep the lid off the pot till the stock comes to boiling point, then keep it on all the time afterwards. After it is well skimmed add the vegetables cut in rather large pieces. After the stock has again reached boiling point, let it just simmer slowly for at least 4 hours. Do not let it boil again; add a little cold water if needed to check the boiling. When done enough, strain through a colander; when cold remove the fat from the top. There will be a thick jelly underneath. This jelly may be used as the basis of different kinds of soups. If you want it clear, and the stock is not clear enough by straining, it may be cleared by using $\frac{3}{4}$ lb. lean beef to each quart of stock, together with some cut up vegetables. Or use the white and shell of 1 egg to each quart of stock, whisk all together over a slow fire till boiling, then let it simmer for about half an hour, strain through a fine tea cloth dipped in boiling water. The albumen in the egg, or the meat added, attracts all the impurities in the liquid and clears it. The stock must be good and strong, as in the process of clearing, especially if the egg be used, some of the value of the soup will be removed. So it is better not to have it cleared; it is more nourishing left as it is. Most soups are better if left for the second day, but they must not be cooked too long after they get hot. Do not cover either cold stock or cold soup. If required to keep for any time, boil up stock daily. Many elaborate soups can be made, but if good beef and bones and vegetables are used, and the stock is made well, using split peas, rice, sago, and corn flour for thickenings, we can reduce our meat bill, and still have good wholesome food. A good way to use split peas is to soak them in cold water over night, then add them to cold stock and simmer for 5 or 6 hours, and then serve. If any one would like recipes for Asparagus Soup, Cocoanut Soup, Mushroom Soup, Mock Turtle Soup, Oyster Soup, or Lobster Soup, I will be pleased to give them.

DAIRYING.

[By Miss R. E. BLUMSON, Laura Bay.]

The care of cows is a very important factor in dairying. All milking cows should have as much water as they will drink twice every day. They should be fed according to the amount of feed in the paddock. If there is plenty of green feed in the paddock they will not need so much chaff, &c. Plenty of chaff and oats must be fed to the cows when paddock feed is scarce. Salt or super is very good sprinkled on the feed, especially where cows are lame and miserable, caused generally through mineral deficiency. Cows can be fed before or after milking, whichever is most convenient. The cow yard should be clean, large, and sheltered from cold winds. They can be fed in nose bags or large boxes. Have nose bags $\frac{3}{4}$ parts full, and add a 5 lb. jam tin of oats (more or less, according to the amount of paddock feed).

Cows must not be ill-treated. Breaking in young cows is quite an easy task if one goes about the job gently. In any case, there should be no trouble at all if the young cow has been petted and treated kindly from a calf. Ill-treatment is the source of nearly all the trouble. The cows must be milked regularly, and their teats washed in warm water, and dried with a clean cloth before milking. Every care must be taken when a cow has cow pox or any skin ailment. Massage the cow's udder with Sulphur Ointment, and be very careful not to handle other cows after milking one with any contagious complaint.

Calf feeding is a very important part of the dairyman's work, especially where heifers are concerned. Regularity in the feeding of calves must be practised to make a success of it. Young calves should be fed on fresh milk for at least a week, and at the present price of butter it pays to give them the good milk for three weeks, and then to slowly reduce the quantity of good milk (substituting separated milk) until they are about 6 weeks old. There is not much nourishment in skim milk, therefore a little linseed is sometimes necessary, or two or three eggs beaten up in the milk when eggs are cheap is very good. Calves should be kept on milk until six months old, and, of course, given chaff and hay as soon as they will eat. The calf pens should be sheltered; preferably made with picket fences, and a roof over half of it. Do not let the calf pen get muddy in wet weather. If there is any green feed around, the calves ought to be tied up to a stake, in a different place each day, so they can get fresh grass.

Cleanliness is essential in all stages of butter production. Separator, strainer, buckets, &c., must all be washed thoroughly in lukewarm water, using a clean dish-cloth and a good brush. All the crevices must be thoroughly cleaned with the brush. All utensils must then be scalded with plenty of boiling water, and then dried with a perfectly clean towel, and put in the bright sunshine when the weather is fine. The Separator needs a certain amount of attention, too. It must be oiled well every day, and kept perfectly clean inside and out. Every little while the inside of the machine must be all cleaned out, as the oil gets thick and clogs the works, thus making it hard to turn. A very good cover to keep the dust out of the separator when not in use can be made from a sugar bag.

Never run warm cream from the Separator on to cold cream. Cream must be stirred every day, and will need to stand 24 hours mixed all together before being churned. In the hot weather it is advisable to do the butter early in the morning. Always avoid having the cream in contact with fruit, vegetables, or anything with a strong odour, all of which spoil the flavour of the butter. It is necessary to churn three times a week in summer and twice in winter. Good butter cannot be made from stale cream. Churn the cream till the butter milk starts to come, then add a tablespoonful of salt to every 6 lbs. butter, dissolved in a cupful of cold water. Churn until a solid lump, then drain off butter milk, and wash until water pours off clear. Roll and sift the salt (1 dessertspoonful to each pound of butter) and work in thoroughly. Then wet butter board, pats, scale tray, &c., and rub salt well in. Turn butter on to board, and knead well with a piece of clean linen, kept specially for the purpose. The linen cloth must be scalded, and dipped into cold water before using to absorb the moisture from the butter. When quite free from moisture, form into pounds, which should be a half ounce overweight, to allow for shrinkage, lay on butter paper, and wrap up neatly. The articles used in butter making must be well scalded and kept in a cool place away from dust and flies.

THE DANGER OF FLIES IN THE HOME.

[By Mrs. M. E. BOWELL, Laura Bay.]

That flies are active carriers of diseases is well known; but I am afraid we are not so careful to keep the plague down as we should be. They breed so quickly in hot weather, especially in stables and pigsties, or wherever manure and moisture collect,

that strong measures are necessary to keep them down. They come to the house on people's backs, and stay with us as long as they are allowed to live. Nothing gives the housewife more trouble than flies, for they pollute everything they touch, and one has to be careful to protect food and milk, as a few flies settling on food, even for a moment or two, may cause illness. They carry germs from sick people, such as influenza, fevers, measles, colds, dysentery, and diarrhoea. Many children die of diarrhoea every year, most likely through infection by flies. They also poison uncovered sores, and are very dangerous to babies and small children, and so persistent that it is most difficult to protect them from the fly pest at times.

We should try to eradicate them from our own homes as much as possible. It is rather difficult on farms, but by burning dead animals, and cleaning stables and pigsties, much can be done to lessen breeding grounds. I think everyone should have fly screens and doors, even if they have to do without something else to get them, as it is quite impossible for a woman to combat the fly plague if flies have free access to the house. For the windows, cheese cloth, on light frames, is better than nothing, but screen doors are as great a necessity as a table in the kitchen. There are several good sprays on the market. After using them, sweep up flies and burn them. I use the "fly swat" and find it effective, both inside and out under verandah and outside of screen doors. Flies usually come in for a warm corner towards evening, and are drowsy, so can be easily "swatted," otherwise they are there early next morning, ready to pop in as soon as one opens the doors. The long sticky papers to hang up are useful, but if flies are very numerous the quicker way is to moisten fly paper. Milk, with a little sugar and formalin, in saucers also acts quickly and surely, as flies are thirsty pests. The materials are poisonous, so must be kept out of children's reach. Ducks are good fly eradicators, and our stables were practically free of flies when we had two Muscovy ducks.

AUBURN (Average annual rainfall, 24in.).

May 25th.—Attendance, 14.

BISCUIT RECIPES.—The following recipes were read by members, who also brought samples of the biscuits:—*Biscuits* (Mrs. Glover): 8ozs. flour, 4ozs. each sugar and butter, 1 egg, 1 tablespoon water. Beat butter and sugar, add the yolk of egg beaten with water, add flour. Top—4ozs. icing sugar, white of an egg, and cocoanut. Mix icing sugar with whole of egg, spread over the dough (which has been rolled out $\frac{1}{4}$ in. thick), sprinkle with cocoanut or chopped almonds, cut into lengths 3in. long, $\frac{1}{4}$ in. wide. Bake in moderate oven. *Ujarganappy* (Mrs. Burfield): $\frac{1}{2}$ cup melted butter, $\frac{1}{2}$ cup sugar, 1 egg, 1 cup cocoanut, 5 small cups cornflakes. Method: Beat butter and sugar together, add egg, then cocoanut, and mix well with cornflakes. Use fairly hot oven; bake in cake containers. *Afternoon Tea Biscuits* (Mrs. Kirkbright): 1lb. S.R. flour, $\frac{1}{2}$ lb. sugar, $\frac{1}{2}$ lb. butter, 2 eggs, a little milk if required. Mix butter and sugar to a cream, add eggs beaten well, lastly flour, essence to taste; roll out, cut with a cutter, and bake on a floured tray in rather a quick oven. *Cinna Coa* (Mrs. Morcom): 2 cups S.R. flour, $\frac{1}{2}$ cup sugar, $\frac{1}{2}$ lb. butter, 1 egg, 1 teaspoon each cinnamon and ground ginger, $\frac{1}{2}$ cup desiccated cocoanut, 1 dessertspoon golden syrup. Melt butter and beat all together. Add a little milk if too stiff. *Monte Carlo* (Mrs. Tansell): 4ozs. butter, 3ozs. sugar, 1 egg, pinch of salt, 1 tablespoon coffee essence, $\frac{1}{2}$ teaspoon vanilla essence, $\frac{1}{2}$ lb. self raising wholemeal flour. Cream butter and sugar, add egg, then essence and wholemeal. Put in teaspoonsful on slide, shape with back of fork. When cold, join with filling made of 3ozs. icing sugar beaten with 1 $\frac{1}{2}$ ozs. butter, 1 teaspoon coffee essence, and a few drops vanilla. *Shortbread Creams* (Mrs. Kelly): Cream well together $\frac{1}{2}$ lb. each butter and sugar, 3 eggs well beaten, and mix well with 1lb. S.R. flour and pinch of salt. When cold, join together with butter icing; one half may be coloured with cochineal. *Chocolate Cream Biscuits*: 12ozs. flour, 6ozs. each butter and sugar, 2 eggs, 2 tablespoons cocoa, $\frac{1}{2}$ teaspoon carbonate soda, 1 teaspoon cream of tartar, $\frac{1}{2}$ teaspoon vanilla, 1 tablespoon milk. Method: Cream butter and sugar, add eggs well beaten, then milk and flour, &c., well sifted. When cold, join together with icing made as follows:—1oz. butter, 1 cup icing sugar, 1 tablespoon boiling water flavoured with vanilla. *Ginger Snaps* (Mrs. Kench): 1lb. flour, $\frac{1}{2}$ lb. each treacle and sugar, $\frac{1}{2}$ lb. butter, $\frac{1}{2}$ oz. ginger, 1 teaspoon carbonate soda, a few drops of essence of lemon. *Walnut Wafers* (Miss Dennison): 3ozs. S.R. flour, 2ozs. each butter, sugar, and walnuts, 2 eggs, vanilla essence. Cream butter and sugar together, add eggs

and sifted flour, beating well. Chop walnuts finely and add with a little vanilla. Drop in small spoonful on a greased baking sheet not too near together. Bake in quick oven 10 minutes. (Secretary, Miss L. Dennison.)

BALUMBAH.

May 12th.—Attendance, 12.

RECIPES.—*Orange Marmalade*.—(Mrs. V. van Heythuysen): 3lbs. poorman's oranges, 13 cups water, 10lbs. sugar, 3 lemons, juice and pulp only. Cut oranges in thin slices, then add water and lemon juice and boil until tender. Stand over night, then add sugar and boil 25 minutes. *Almond Slices*.—(Mrs. Murphy): 7ozs. flour, 4ozs. butter, 4ozs. sugar, 1 teaspoon baking powder, 4ozs. almonds, 2 eggs, cream butter and sugar, add eggs, beating each in separately. When mixture is light, add sifted flour and about 3 parts of blanched almonds, finely shredded. When the last two ingredients are thoroughly mixed in, pour into shallow baking tin, spreading it well out. Split remaining almonds and scatter over top of cake, rounded side up. Bake in a moderate oven 15-20 minutes. When cake is coloured nicely turn out on to sugared paper, and cut in fingers when cold. *Nut Rolls*.—(Miss V. Wohling): 2 cups S.R. flour, 2 cups wholemeal, $\frac{1}{2}$ cup sugar, 1 cup sultanas, 1 cup dates, 6ozs. nuts (chopped), 1 teaspoon salt, 2 tablespoons each treacle and butter. Mix thoroughly flour, wholemeal, sugar, sultanas, dates, nuts (walnuts for preference), and salt, then add treacle and butter, which has been well heated and mixed in a saucepan. Mix well into the dry ingredients, and if too stiff add a little milk, but leave mixture as stiff as possible. Fill greased cocoa tins about 3ins. from the top, put on lids and bake in a moderate oven for about 20 minutes, with the tins standing up, then lay them down long ways, and bake 1 hour, turning every $\frac{1}{2}$ hour. When cool, cut in thin slices and butter. *Wheatmeal Scones*.—(Miss H. Jericho): 4 cups S.R. flour, 1 cup wheatmeal, 4 tablespoons cream, a pinch of salt, and enough milk to mix into a nice paste. Roll out lightly, cut in shapes, and bake 20 minutes in a hot oven. *Whole Meal Bread*.—(Mrs. H. Ellis): Take 2 large cups wheat, cover with water and boil well. When cool, put through an ordinary household mincer. Ingredients: 3 cups minced wheat, 4 cups white flour, 1 dessertspoon treacle, 1 teaspoon salt, $\frac{1}{2}$ cup yeast, little water to mix. Make as for ordinary bread, allow to rise, knead, and allow to rise a second time. Knead again and put into tins to rise. When ready, bake for not less than 1 hour. It is essential that the dough be kneaded three times and be sure to include the treacle. *Eccles Cakes*.—(Mrs. J. Swann): $\frac{1}{2}$ lb. flaky pastry, 2ozs. butter, 4ozs. each brown sugar and currants, 1oz. candied peel. Put butter in saucepan and melt, cut peel in fine pieces, then add currants, sugar, peel, and also a little grated nutmeg, and stir all together. Cut pastry into rounds, put some of the mixture, fold edges over, then turn over and roll until currants can be seen. Moisten top and sprinkle with sugar, bake in a hot oven 15 minutes. *Bread, made with Wild Hops*.—(Mrs. J. Franklin): First dry the wild hops, then take twice as much as ordinary hops make yeast in the same way, and also the bread. There is no difference in the bread made this way and with the shop-made hops.

SMOCKING.—Paper read and illustrated by Mrs. Murphy:—"Smocking is a very effective trimming for children's and women's clothes. It is very smart and easy to do. Many dainty and colourful garments can be made at a small cost. The simplest form of smocking is done on flat material. A transfer is obtained and stamped on with a warm iron. It is not strictly necessary to have a transfer, for with the aid of a pencil and ruler a suitable one can be made. It is necessary to make the transfer two-thirds larger than needed, as work usually smocks to about one-third of the original—therefore, if 2ins. of smocking are required it is necessary to have 6ins. of transfer. First begin working with tacking stitches, picking up each dot. When this is finished the work must be drawn together tightly—the tighter the better, because it is much easier to work. The appearance of the work is a series of small pleats with a dot on the top of each pleat. The material is now prepared for working. Thread needle with colour needed and work along each pleat with a stem stitch. This stitch holds the pleats firmly together. Continue working along or between rows with any stitch preferred and finish off work with stem stitch. Circular smocks are very dainty. To do these, have a special transfer, and then it is drawn and worked as desired. Circular smocks, smocked in different colours and stitches with a row of dainty-coloured roses and leaves in between make beautiful frocks for baby girls and smart blouses for girls and women." (Secretary, Miss V. Wohling.)

BELALIE (Average annual rainfall, 17.7in.).

May 8th.—Attendance, 23.

Sister Gurry of the Jamestown Hospital demonstrated an infant's layette showing the advantages of modern garments against old-fashioned baby clothes. From the discussion it was learned that infants' clothing should only be blue once a week and soda must never be used in washing. Vioella wool was recommended as best for knitting infants' garments. (Secretary, Mrs. A. Cummings.)

CLARE (Average annual rainfall, 24.56in.).

May 5th.—Attendance, 29.

ENTERTAINING YOUNG AND OLD.—Mrs. H. Bowley in the course of an address on this subject said entertaining meant to engage the attention agreeably, to amuse with that which makes the time pass pleasantly, or to divert or to receive into one's home. Entertainment was provided even for baby age, rattles, toys, &c., then to the kindergarten stage and from there to school days. After school hours childrens' playgrounds were the source of entertainment to most children. Libraries were another form for the older child. Picnics were a healthy source of entertainment. Then in high school life there were sports clubs as well as the scholastic side. After school life there were sports to entertain, community singing, music, bridge, knitting, and if older, conversation. Mrs. Deland also spoke. She said at one time sport was only considered for the young but now-a-days quite elderly folk took part in croquet, bowls, and bridge. One had only to go to the beaches during summer to see people of all ages getting entertainment and variety out of mixed bathing. When summed up "We are only as old as we feel." The shingled head as well as modern fashions were also adopted by many elderly folk. There were compensations for the really elderly folk, they had store houses of reminiscences which were the resting places of many recollections. The best and kindest way to entertain the old was to allow them to do the entertaining. Listen to them patiently and intelligently, thus they will be pleased and the listener will find that his time has not been spent in vain. (Secretary, Mrs. A. Pollock.)

LAURA BAY.

May 8th.—Attendance, 13.

PASTRY.—Paper read by Miss T. Barnett:—"There are three kinds of pastry:—Short crust, so-called because short and crumbly when cooked, used for Cornish pasties and all fruit pies, except apple pie; flaky pastry, so-called because in flakes or layers when cooked, used for apple pie and all meat pies, except Cornish pasties; suet crust, made with suet as shortening, used for boiled pudding, boiled dumplings, &c. Pastry should be made in a cool, airy place, put on a clean, cold oven slide, and baked in a hot oven. See that the oven is hot for flaky pastry or short crust, and the saucepan of water boiling for suet crust. Sift flour, salt and baking powder to remove lumps, mix thoroughly, and enclose air. Rub fat into flour with tips of fingers, raising fingers out of flour so that the air may mix with the flour as it falls. Handle pastry as little as possible, but lightly and quickly. Do not knead short or suet crust; use as little water as possible; the dough must be stiff and in one lump. Make dough for puff pastry fairly moist, and knead it well before adding fat. Roll pastry with a firm even pressure away from you—never sideways. Pastry should not be put over the contents of a pie whilst hot; the steam will make the underlayers of the pastry sodden. While pastry is in the oven, open the door of oven very seldom—never within

TEARING THEM OUT

is the regular job of the Monkey Grubber; in fact it was born to the work.

TREES and STUMPS, it matters not, they are torn out with roots intact, a thorough job quickly done. Run in the job like a bare track, and worked in the same manner as a boat is rowed. It develops the power of 200 men, progressively applied, and always under perfect control.

In any position, so long as the operator has space for a footing, the machine is efficiently worked. An Automatic Gear allows a load to be hauled or released at will. Besides the great power and portability there are embodied other labour saving features, such as special rope couplings, rope shortener, snatch hook, etc.

Agriculturalists in Australia, New Zealand, Great Britain, South Africa, the Americas, as well as Planters in India, China, Central Africa, F.R.S. the East and West Indies, recognised its merits and applied its help.

THE "MONKEY" GRUBBER

is fashioned from material mined and made within the Empire, by Empire craftsmen, to assist with the full and efficient development of Her Self's resources.

South Australian Farmers Union.

the first five minutes. Small holes should be made in pastry that is covering meat pies to allow the gases from the meat to escape. When pastry is cooked in an open tart tin it should be well pricked to prevent it from rising too high in the centre. *Ingredients for Pastry.*— $\frac{1}{2}$ lb. flour, 1 gill water (cold), $\frac{1}{2}$ lb. fat or suet, $\frac{1}{2}$ teaspoon baking powder, pinch salt. To test oven heat sprinkle a little flour on cold oven slide and place in oven. The flour should become dark brown in 30 seconds, or a piece of paper should turn dark brown in the same time.

RECIPES FOR BISCUITS GIVEN BY MRS. F. EDSON.—*Plain Biscuits.*—Melt $\frac{1}{2}$ lb. butter in $\frac{1}{2}$ pint warm milk, 2 eggs, beat 1 minute. Stir these into $\frac{1}{2}$ lb. flour, make a stiff paste, roll it thin, cut into plain circles the size of the top of a tumbler, and bake 10 to 12 minutes. *Ginger Nuts.*—Rub 6ozs. of butter or good dripping into $1\frac{1}{2}$ lbs. of flour, add 1 teaspoon soda, 2 ozs. powdered ginger, $\frac{1}{2}$ lb. treacle. Make into nuts, bake on greased tins in a moderate oven 15 minutes. Dripping can be used instead of butter. (Secretary, Mrs. Morrison.)

PARRAKIE (Average annual rainfall, 14.64in.).

May 22nd.—Attendance, 10.

FARM LIFE EXPERIENCES.—Paper read by Mrs. Hamilton:—"Most of my life has been spent on a farm, and I have had the usual experience of most rural women. Looking back I am struck with the many changes and different methods of doing things. We feed the cows, milk them, and treat them much the same as 40 years ago, but we deal with the milk and cream in quite a different way. Instead of the old-fashioned, roomy dairy with the milk pans set around for cream we have the separator. Again, we sell the cream, not the butter, and send it to market at once. Years ago we made it into butter with the wooden churn, and sold it where we could. It generally went to the nearest store. Butter prices rose and fell in those times much the same as they do to-day. Poultry were handled much the same as to-day, except that now we hatch with an incubator and keep the chicks warm in a brooder. We buy day-old chicks of high laying strains, and have a much more prolific hen; also different and better ways of disposing of them. We obtain better prices for eggs and poultry than we did 30 years ago, but I have more trouble with tick and foxes to-day. Pigs are very unruly. I like them best in a good sty or on the table. My experience on a farm has been that one can have a garden. One should try and grow most vegetables, kill your own meat, and grind your own porridge meal. Many people think farm life is monotonous, but I have not found it so. We can interest ourselves in many things apart from household duties. At present we have better roads, and with motors more comfort, and are safer when out at night. We trust that the farmer will receive better prices, experience better seasons, and hope always for the best."

Mrs. Temby also read a paper on the above subject. She said her earliest recollections were of happenings and experiences on a farm, and had lived on one for over 50 years. Farm life for some people was much harder than for others. Sidelines she thought the most interesting. At present there was little profit in anything, and it was wonderful that as much interest was shown as when times were prosperous. All realised that farming must continue or everything else would fail. (Secretary, Miss Halliday).

PYGERY.

April 3rd.—Attendance, 9.

THREE COURSE DINNER MENUS AND RECIPES.—Mrs. M. E. Heath: *Chicken Broth*.—Take a small chicken, remove all fat, and cut into small pieces. Put into a saucepan with a quart of warm water and a little salt. Simmer over fire for 2 hours slowly, then strain. Serve with small squares of dry toast and add a little parsley before serving. *Poor Man's Duck*.—Remove bone from shoulder of mutton. Make stuffing of bread crumbs and onions, and seasoning to taste. Fill the hole and tie, and bake 2 hours. Serve with cauliflower and white sauce, and brown gravy. *Queen of Puddings*.—1 pint of bread crumbs, 1 quart of milk, 4 eggs (the yolk), a piece of butter the size of an egg, sugar to sweeten, flavour with lemon. When baked spread with jelly or jam and the white of the eggs beaten to a stiff froth. Mrs. A. R. Kammermann: *Tomato Soup*.—Boil several tomatoes and 1 onion finely cut. Strain, and add to the juice 1 cup hot new milk and 1 cup of stock; salt and pepper to taste, and thicken with a little flour. *Mock Fowl*.—Take a loin of mutton with sufficient chops to allow one for each person. Make a basin of seasoning, lay it on the chop side, turn the flap over and sew around the edge. Roast and serve cold with salad. *Stewed Pears with Blanc Mange*.—Let the sugar and water boil for 20 minutes before putting in the fruit. For blanc mange, allow to each pint of new milk 1 tablespoon each of sugar and corn flour, beat these in a basin with a little cold milk. Bring the rest of the milk to boil, pour it on the mixture in the basin, and beat until smooth. Serve quite cold. Miss G. Haylen: *Cauliflower Soup*.—1 cauliflower, 1 table-

spoon flour, 1 pint stock, 1 tablespoon margarine, $\frac{1}{2}$ cup of milk. Wash the cauliflower and break into small pieces, and boil in stock until quite soft. Follow by melting margarine and working the flour into it. Then mix the cauliflower, stock, the floured margarine, and the milk. Heat for 30 minutes, and add salt and pepper to taste.

Roast Pigeons.—Plunge pigeons in a saucepanful of hot fat, let them cook slowly for $\frac{1}{2}$ hour, then take out and brown in the oven for 10 minutes, or more if necessary.

Chip Potatoes.—Cut raw potatoes into slices, the thickness should be $\frac{1}{4}$ in. Melt some well clarified beef dripping in the frying pan, when very hot put in potatoes and fry for about 5 minutes, turning them as they brown. When cooked drain well and sprinkle with salt and pepper.

French Beans.—Use the old fashioned beans. Take off the outer rind, but do not cut up, tie in a bundle like asparagus and boil, serve with melted butter.

Apple Charlotte Russe.—Melt 2ozs. gelatine in $\frac{1}{2}$ cup of water, add a little sugar, lemon juice, and carmine. Put a layer of this in a plain mould and let it set, then line the sides of mould with finger biscuits and pile with following mixture:—1 cup of apple pulp flavoured with lemon juice and a little grated rind. Put in 4 sheets of gelatine (which has been melted in a very little water and allowed to cool slightly) the whites of 2 eggs stiffly beaten, and enough castor sugar to sweeten the mixture. Colour half with pink and put in mould, then colour the other with green and pile up rest of mould and put aside to get thoroughly cold. Turn out and decorate with whipped cream. (Secretary, Mrs. E. I. Heylen.)

May 1st.—Attendance, 16.

RECIPES FOR SWEETS.—The programme consisted of a display of sweets and recipes.

Snow Balls (Miss R. V. Foster): Soak 1oz. of gelatine in 1 $\frac{1}{2}$ gills water 20 minutes. Boil together 1lb. sugar, 1 $\frac{1}{2}$ gill of water, boil until sugar has dissolved; add gelatine and water, boil 10 minutes longer. Pour mixture into a bowl to cool, cut or roll in cocoanut.

Caramels: 1 large breakfast cup sugar, 1 level tablespoon flour, stir well together, then add a piece of butter the size of an egg, 2 tablespoons golden syrup, $\frac{1}{2}$ cup milk. Boiling quickly, this takes $\frac{1}{2}$ hour to cook, stirring all the time.

Toffee: 1 large breakfast cup sugar, 2 tablespoons honey, $\frac{1}{2}$ cup milk, boil 20 minutes quickly.

Cocoanut Ice (Miss M. C. Kammermann): 2 breakfast cups sugar, $\frac{1}{2}$ cup milk, 1 cup desiccated cocoanut. Boil sugar and milk in an enamelled saucepan slowly for 5 minutes, stirring all the time, then add desiccated cocoanut and boil for 1 minute. Take off saucepan and set it in a dish of cold water and stir until thick. Put half in a wet soup plate, colour the other half and spread on top.

Toffee (Mrs. W. H. Douglass and Miss O. Ingram): 2 cups sugar, $\frac{1}{2}$ cup water, boil until it sets in a little cold water.

Chocolate Ruffs: 1 cup each icing sugar and scorched cocoanut, 2 tablespoons cocoa. Mix with enough cream to make firm.

Almond Toffee (Mrs. M. E. Heath): 2lbs. sugar, 2 cups water. When boiling add $\frac{1}{2}$ saltspoon cream tartar dissolved in 1 tablespoon water. Let boil hard without the lid, to cracking degree, or when it begins to change colour. Sprinkle with blanched almonds and pour into a greased dish.

Turkish Delight (Mrs. G. Duggin): 1lb. granulated sugar, 1 lemon, 1oz. gelatine, water, icing sugar (cochineal to colour half). Soften the gelatine in a little cold water, then stir over gentle heat until dissolved. Boil sugar with 1 gill cold water, stirring until dissolved, strain in dissolved gelatine, and boil gently for 15 minutes, stirring frequently; draw to the side of the fire and add strained juice of lemon. After 15 minutes, strain and pour half into moistened tin to cool. Colour the remainder and turn into another moistened dish. When cold turn each on to a board dusted with icing sugar, cut into shapes, and roll in the sugar.

Vanilla Cream Caramels: 1lb. sugar, $\frac{1}{2}$ lb. butter, 1 cup each milk and cream, vanilla essence, and 1 tablespoon glucose. Stir sugar, milk, cream, and glucose over the fire until boiling, add butter, and stir; boil to the "hard ball." Flavour with vanilla essence, pour on to a buttered tin and when cool cut into squares. (Secretary, Mrs. E. I. Heylen.)

WILKAWATT (Average annual rainfall, 16 to 17ins.)

May 8th.—Attendance, 14.

HOMESTEAD MEETING.—The monthly meeting took the form of a social afternoon at the home of Mrs. F. R. Koch. Songs were rendered by Mesdames Bowman, Neville jnr., and Mrs. Koch. Mrs. Koch read several useful hints and recipes. (Secretary, Mrs. A. Oram.)

YURGO, May 25th.

WINTER PUDDINGS.—Paper read by Mrs. Rogers:—"As the various fruits and their accompaniments are mostly favoured for summer sweets, one looks forward to something more substantial for winter fare, such as steamed or boiled puddings which contain suet, butter, or dripping are usually boiled in a cloth or steamed in a greased basin, and are both wholesome and appetising. If I have a roast dinner I usually

have a boiled or steamed pudding, such as some of the following:—*Mother's Currant Pudding*.—1 cup sugar, 1 tablespoon dripping, pinch salt, $\frac{1}{2}$ cup milk, 1 cup each bread-crumbs and plain flour, $\frac{1}{2}$ teaspoon carb. soda, few currants or sultanas and little lemon peel. Mix all dry ingredients except soda, bind with milk, add soda dissolved in little boiling water, put in cloth already scalded and well floured, place in saucepan of boiling water, into which a saucer has been dropped. Boil $2\frac{1}{2}$ hours. I usually double this quantity, and what is left from dinner I fry for tea; cut in slices and fried in hot butter (or dripping), well drained and sprinkled with sugar, it is delicious.

Jam Roly Poly.—I used to have trouble with this sticking to the cloth, but have overcome that difficulty by first wrapping in greased butterpaper before tying in scalded cloth, and it turns out as desired. I put breadcrumbs in my mixture; it adds to the lightness of the pudding. Recipe is as follows:— $\frac{1}{2}$ lb. each breadcrumbs, flour, and suet, $\frac{1}{2}$ teaspoon salt, 1 teaspoon baking powder, water to mix. Mix dry ingredients, add shredded suet, rub well, mix to stiff paste, roll out in long strip, spread with jam, keeping it away from the edges of pastry; roll up and seal ends, roll in greased butterpaper, then in scalded cloth. Cook in boiling water two hours or more. Serve with boiled custard or cream.

Sago Fruit Pudding.—The sago fruit pudding is a general favourite, preferably for Sundays; on account of it being so rich one only needs a small serve. 1 cup breadcrumbs, 2 large tablespoons sago (soaked in enough milk to cover, soak over night), $\frac{1}{2}$ cup sugar, 1 cup seeded raisins, 2 tablespoons butter, 1 teaspoon soda dissolved in boiling water. Mix with enough milk to make rather slack; boil three hours or more. For steamed puddings, the college pudding and the 30 minutes pudding is my standby for washing days. It is easily and quickly made, and takes only 30 minutes to cook. I cook it in the same basin in which it is mixed. Scrape the mixture tidily from the sides of the basin and place in saucepan quarter full of boiling water and cook 30 minutes.

Thirty Minute Pudding.—1 cup S.R. flour, 1 pinch salt, 1 dessertspoon each butter and sugar, 1 egg, about $\frac{1}{2}$ cup milk. Beat butter and sugar, add egg, then milk and flour to make stiff batter. Serve with golden syrup and cream or sweet white sauce. I never cover the steamed puddings with greased paper or such like, and never have trouble with water getting into them if careful how I lift the saucepan lid. I try to find a convenient spot on my stove for the pudding saucepan, where it will keep simmering, and avoid shifting it if possible. If I have a boiled dinner then I arrange a baked pudding—either mill puddings, baked jam roll, or cottage pudding.

Baked Jam Roll.—2 cups S.R. flour 2 tablespoons dripping, pinch salt, water to mix; rub dripping well into flour and salt; mix to stiff paste with water, roll out, spread with jam. Roll up, place in greased piedish. Into a basin put a tablespoon butter, $\frac{1}{2}$ cup sugar, dissolve with 1 cup boiling water, pour over jam roll, bake in moderate oven $\frac{1}{2}$ hour, basting with the syrup occasionally." (Secretary, Mrs. R. Sanders.)
